Volume I Response to Comments on the SDEIS

Laws and Regulations

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Elizabeth Barnes	6652	27	4-224 Why are the IDPES Cyanidation Permit limits and requirements not incorporated into the analysis and final impact statements? The argument that fish habitat will be increased is a negligent statement given the exclusion of this data.	REG	Idaho Cyanide Permits are prepared individually for each application and permit conditions and limits are based on the site-specific characteristics of the proposed operations, their operating and closure procedures, and the natural conditions at the project site. At the time this SDEIS was prepared the permit limits and requirements had not yet been established by IDEQ. This was clearly stated in the last sentence of the IPDES Permits and Cyanidation Permit subsection on page 4-224.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	12	<p>III. THE SDEIS IS BASED ON THE WRONG REGULATORY STRUCTURE</p> <p>The Forest Service is under the mistaken belief that its review and approval of Perpetua’s proposed uses of federal land are authorized by the 1872 Mining Law and governed solely by the agency’s hardrock mining regulations at 36 CFR Part 228 Subpart A. SDEIS at 1-8. According to the Forest Service, this is because there are unpatented mining or millsite claims on the lands to be covered by project facilities. The SDEIS also states that the existing Forest Plan must be amended to accommodate the company’s plans, based on Perpetua’s presumed “rights” under the Mining Law.</p> <p>According to the Forest Service, its authority is limited by the company’s purported and asserted “rights” under the 1872 Mining Law. 1872 Mining Law (as Amended) -The statutory right to search for, develop, and extract mineral deposits on federal lands open to mineral entry was established by the Mining Law and later legislation. These rights include the right to initially locate a mining claim and the right to reasonable access to the claim for further exploration, mining, or necessary ancillary activities, consistent with the Mining and Mineral Policy Act of 1970 (30 United States Code [USC] 21a) and other applicable laws.</p> <p>SDEIS at 3-3. See also SDEIS at Section 1.6.1.(SDEIS at 1-8)(“The Forest Service’s purpose is to consider approval of Perpetua’s proposed use of the surface of NFS lands in connection with operations authorized by the U.S. mining law as first described in the Plan submitted September 2016, then refined in 2019 (Brown and Caldwell 2019a), and further modified in 2021 as the 2021 MMP (Perpetua 2021a))(emphasis added). This tracks the initial DEIS’ statement that the agency’s review of the project was based on the company’s “statutory right” to conduct its operations under the Mining Law.</p> <p>3.2.2.1 1872 Mining Law The statutory right to search for, develop, and extract mineral deposits on public-domain lands open to mineral entry was established by the General Mining Act of 1872 (1872 Mining Law) and later legislation. These rights include the right to initially locate a mining claim and the right to reasonable access to the claim for further exploration, mining, or necessary ancillary activities, consistent with the Mining and Mineral Policy Act of 1970 (30 United States Code 21a) and other applicable laws. As described elsewhere in this EIS, regulations at 36 Code of Federal Regulations (CFR) 228, subpart A apply to U.S. Forest Service (Forest Service) regulation of surface use of National Forest System lands for locatable mineral operations. DEIS at 3.2-1.</p> <p>The mere fact that the company submitted a mining plan does not mean that all, or any, aspects of the project that remain in federal ownership are regulated only under Part 228 or that approving the plan is the Forest Service’s only choice. Indeed, because the record lacks the requisite evidence that the company has statutory rights under federal mining laws, including the 1872 Mining Law, to the lands that remain in federal ownership, review and regulation of the project is not under Part 228, but rather the agency’s special use and multiple use authorities (36 CFR Part 251/261), including right-of-ways (ROW) under the Federal Land Policy and Management Act (FLPMA).</p> <p>The Forest Service’s overly-restricted interpretation of its authority was squarely and recently rejected by the Ninth Circuit Court of Appeals, which has jurisdiction over Idaho. On May 12, 2022, the court issued its decision in Center for Biological Diversity v. U.S. Fish and Wildlife Service, in which the</p>	REG	<p>The Forest Service is not assuming the validity of the mining claims included in the SGP. The status of the mining claims for the area of the SGP is described in Section 4 and Appendix II of the 2021 Feasibility Study Technical Report which was prepared in compliance with the National Instrument 43-101 of the Canadian Securities Administrators Standards (NI 43-101) for reporting mineral properties (M3, 2021). The purpose of NI 43-101 is to ensure that misleading or erroneous information on mineral properties is not published or represented to potential investors on the stock exchanges overseen by the Canadian Securities Authority. A 43-101 feasibility study is a comprehensive technical and economic description of a mineral project prepared by experts who must have the prerequisite qualifications (“Qualified Persons”).</p> <p>Section 4 of the Feasibility Study describes the mineral title of the SGP property in some detail. It references a legal opinion prepared by a well-known law firm with expertise in these matters, Parson, Behle & Latimer. The report also states, “no significant flaws or title issues have been identified in multiple formal title reviews of the claims performed by qualified, independent, title examiners”.</p> <p>This report describes the mineralization at the SGP property and the location of the mineral resources to be mined on patented and unpatented mining claims within the property. The report also states that, as of the effective date of the report, December 2020, the property taxes were paid in full for the patented mining claims. Maintenance of the unpatented mining claims requires that the BLM be provided with the serial numbers and evidence of maintenance fees of the claims on or before September 1 of each year. The report states that this was completed for the most recent filing year prior to release of the report on August 3, 2020, and that an Affidavit of Satisfaction was subsequently recorded with Valley County on August 20, 2020. This information can be considered reliable evidence that the subject claims are properly authorized by the 1872 Mining Law.</p> <p>The Feasibility Report was cited in the SDEIS and is part of the Project Record. The property ownership information of the report has been reviewed by the Forest Service and determined to be reliable.</p> <p>Based on the reliable property ownership description in the Feasibility Study Technical Report, the Forest Service believes the SGP is properly regulated under the 36 CFR Part 228 regulations.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>court affirmed the district court decision that vacated and remanded the Forest Service’s approval of a large copper mine (the Rosemont Mine) due to the agency’s erroneous interpretation and application of the 1872 Mining Law, federal public land law, and NEPA.</p> <p>The court squarely rejected the same federal government position taken by the Forest Service in the SDEIS – that mining claimants are entitled to use and occupy mining or millsite claims absent any evidence that the claims are valid under the Mining Law, and that the Part 228A regulations are the only proper regulatory vehicle for operations proposed on such lands/claims. The court ruled that the government’s statutory interpretation was contrary to the plain language and controlling case law under the Mining Law, Organic Act, NEPA, Surface Resources Act of 1955 (30 U.S.C. Section 612), and other laws. The Rosemont decision rejected the government’s position that it has no authority to apply its broader public land regulations to mining operations proposed on lands that fail to meet the Mining Law’s statutory prerequisites for rights against the United States.</p> <p>The agency’s review of the Stibnite Gold Project is based on the erroneous legal view that the entire project is authorized by the 1872 Mining Law and can only be regulated by the Part 228 Subpart A regulations simply because it involves uses of federal land related to mining. Here, although it is difficult to ascertain the exact number and nature of the claims from the SDEIS, the Forest Service believes that it is precluded from choosing the no-action alternative, as well as being significantly restricted in its review authority over the Project.</p> <p>In regard to Stibnite, the agency recently stated that the “228A regulatory framework was applied pending additional guidance from counsel. No validity assessment of unpatented claims was incorporated per Forest Service practice.” USFS – Stibnite Gold Project SDEIS Comment Response Table – 20 October 2022, at 1.</p> <p>Yet the Ninth Circuit ruled that this Forest Service position erroneously interprets the 1872 Mining Law as well as other public land and mining laws. The court held that unless sufficient evidence exists in the agency record that the claims proposed for use and occupancy met the requirements of the Mining Law and were therefore valid—that is, each mining claim must contain the requisite “valuable minerals,” and each millsite claim must meet the strict requirements of Section 42 of the Mining Law, including the requirement that the lands are nonmineral and do not exceed the allowable number of valid millsites, which are limited to a strict 5 acres of millsites (the maximum size for each millsite claim) for each full size mining claim (20 acres)—the Mining Law did not govern the agency’s review of the proposed use/occupancy of those lands. Simply put, unless each claim is shown to be valid and meets all factual and legal requirements, the Forest Service cannot simply assume rights under the Mining Law that limit the federal land agency’s full and broad authority to protect public land and resources.</p> <p>The Ninth Circuit also held that the agency’s failure to inquire into whether the claims covering the ancillary uses (such as waste dump and tailings) were valid under the Mining Law was essentially the same as assuming the claimant had a right to use and occupy these lands – and that such an assumption illegally created statutory rights where none exist.</p> <p>In the FEIS, the Service either assumed that Rosemont’s mining claims on that land were valid or (what amounted to the same thing) did not inquire into the validity of the claims. Based on its assumption that the mining claims were valid, the Service concluded that Rosemont’s permanent occupation of the claims with its waste rock was permitted under the Mining Law.</p> <p>“The Government’s argument is not only foreclosed by the text of Section 22. It is also foreclosed by a century of precedent.”</p> <p>At Rosemont, the issue was the validity of the mining claims. At Stibnite, while the company recently refiled millsite claims on much of the project’s lands, the court’s requirement is the same – the agency cannot assume that the company has rights to use/occupy these lands without verifying that each claim meets the validity requirements in the Mining Law (whether for lode or millsite claims). As noted, the agency’s failure to inquire as to whether the claims are valid fundamentally flaws the entire SDEIS and agency review.</p>		

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>The Forest Service’s review of the Stibnite proposal is very similar to and based on the same legal positions as its illegal review of the Rosemont Mine. The Arizona court detailed how the agency never inquired into whether the mining claims away from the mine pit met the Mining Law’s prerequisite for use/occupancy rights (discovery of valuable minerals), yet the agency “accepted, without question, that those unpatented mining claims were valid” and “assumed that Rosemont had the right to use those 2,447 acres to support its mining operation (i.e., by dumping 1.9 billion tons of waste on that land).” “This was a crucial error as it tainted the Forest Service’s evaluation of the Rosemont Mine from the start.” The court held that such use/occupancy, without verification that such rights under the Mining Law actually exist on those lands/claims, was not authorized by the Mining Law, and thus was not governed by the agency’s mining regulations.</p> <p>The situation is the same here, as there is nothing in the record that provides “a factual basis to support [the claimant’s] assertion of rights.” Under basic principles of administrative law: “Any decision made without first establishing the factual basis upon which the Forest Service could form an opinion on surface rights would entirely ignore an important aspect of the problem.”</p> <p>Based on the Forest Service’s erroneous view of “rights” under the Mining Law, the SDEIS asserts that only Forest Service mining regulations at 36 C.F.R. Part 228A (which have no public interest requirement and no required compliance with the agency’s multiple use mandate) apply to every aspect of the project. The Forest Service mining regulations at 36 C.F.R. Part 228A only apply to “operations authorized by the mining laws.” 36 C.F.R. § 228.1. The Arizona federal court held that only upon the satisfaction of the Mining Law’s prerequisite requirements for statutory rights against the United States are “operations authorized by the mining laws.”</p> <p>[I]t does not follow that the Forest Service must use these Part 228 regulations merely because an action falls within the regulation’s definition of operations. The Forest Service’s reliance on its definition of operations ignores the purpose of its own regulations. Part 228 regulates “use of the surface of National Forest System lands in connection with operations authorized by the United States mining laws (30 U.S.C. 21-54 [Mining Law of 1872]).” 36 C.F.R. § 228.1. Therefore, authorization under the Mining Law of 1872 acts as a precursor to any regulation through Part 228.</p> <p>As the court held: “the regulations state that mining activities on Forest Service land are permitted only as specifically authorized by the Mining Law of 1872. As Rosemont has no rights under the Mining Law as to the land at issue, it follows that the regulations certainly do not create independent rights that do not exist under the Mining Law.”</p> <p>Here, at Stibnite, since the Forest Service has refused to inquire as to whether all of the mining and millsite claims are valid, the record does not show that the proposed facilities, uses, and associated operations are “authorized by the Mining Law of 1872.” As such, use of the Part 228A regulations, instead of the Part 251/261 special use regulations, is illegal.</p> <p>Regarding whether only the Part 228A regulations applied in such a case, the Ninth Circuit slightly modified the District Court’s remand instructions to the Forest Service, holding that the Forest Service could not rely on “rights” under the Mining Law or the Surface Resources Act:</p> <p>The Service relied on Part 228A regulations in its FEIS and ROD, but it did so based on Section 612 of the Multiple Use Act and on its assumption that Rosemont’s mining claims are valid under the Mining Act. The Government has now abandoned any argument based on Section 612. Further, for reasons explained above, the Service incorrectly assumed that Rosemont’s mining claims are valid under the Mining Law. That is, neither of the statutes upon which the Service relied to support its application of Part 228A regulations to Rosemont’s MPO provides such support. Thus, the Service’s approval of Rosemont’s MPO is unsupported by the basis upon which the Service relied.</p> <p>Due to the agency’s fundamental assumption of rights under the Mining Law, the court instructed the agency as to the proper scope of its authority – given that the agency never determined whether the claims were valid. We do not know whether, if the Service had understood that Section 612 gave no rights beyond those conferred by the Mining Law and that Rosemont’s mining claims are invalid under</p>		

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>the Mining Law, it would have found some other statutory basis to support the application of Part 228A regulations. Nor do we know whether, if it were to rely on some other statutory basis, the Service would construe Part 228A regulations to authorize Rosemont's permanent occupancy of invalid mining claims with its waste rock.</p> <p>In applying Part 228A regulations and relying on their own construction of those regulations to authorize Rosemont's proposed occupancy, the Government, Rosemont, and our dissenting colleague are putting the cart before the horse.</p> <p>The District Court (affirmed by the Ninth Circuit) also rejected the legal position taken by Forest Service here, where it asserts that it cannot choose the No-Action Alternative for the project. In the Rosemont Mine decision, after discussing the agency's erroneous assumption of "rights" under the Mining Law (detailed above), the court discussed how this erroneous legal position also violated the agency's duties under NEPA:</p> <p>Based on the administrative record, the Forest Service improperly applied its Part 228 regulations to actions not authorized under the Mining Law of 1872. This mistake infected the FEIS and led to the Forest Service misinforming the public and failing to consider reasonable alternatives within the scope of its duties under the Organic Act.</p> <p>For example, in response to a public comment requesting the Forest Service "give true consideration to selection of the No Action Alternative", the Forest Service responded: "The Forest Service may reject an unreasonable Mine Plan of Operation but cannot categorically prohibit mining or deny reasonable and legal mineral operations under the mining laws." Id. at G-10 [Final Rosemont EIS]. In response to a comment requesting the Forest Service "consider other locations for copper mining", the Forest Service responded: "The Forest Service lacks the authority to deny Rosemont Copper's proposal if it can be legally permitted." Id. at G-12. And in response to a comment that the Forest Service "should scale down the size of the project or limit it to private lands only", the Forest Service repeated: "The Forest Service may reject an unreasonable Mine Plan of Operation but cannot categorically prohibit mining or deny reasonable and legal mineral operations under the mining laws." Id. These examples did not occur in isolation. Rather, they illustrate how heavily the Forest Service relied upon this rationale in its decision-making process.</p> <p>Under the Part 251 regulations, the Forest Service could limit the mine to any of the above options if it found they ran afoul of the public interest. The Forest Service failed to take the requisite hard look at these alternatives by informing the public that it could not truly consider any alternative that rejected the MPO or substantially modified it as to make the mine economically unfeasible. See Nat. Res. Def. Council, 421 F.3d at 813-14. A "thorough discussion of the significant aspects of the probable environmental consequences" will include the regulatory framework in which the Forest Service analyzes those consequences. See California v. Block, 690 F.2d 753, 761 (9th Cir. 1982). No amount of alternatives or depth of discussion could "foster[] informed decision-making and informed public participation" when the Forest Service bases its choice of alternatives on an erroneous view of the law. See Westlands Water Dist. v. U.S. Dep't of Interior, 376 F.3d 853, 868 (9th Cir. 2004).</p> <p>As the court stated, the agency's erroneous interpretation of federal mining law resulted in a violation of the Organic Act and NEPA. "[A] grant to use the surface when the administrative record shows such a right does not exist would contravene the Forest Service's duty to protect the forest from depredations and offer an opinion that runs contrary to the evidence." "In the absence of any statutory right on the part of Rosemont, the Forest Service could deny Rosemont's off-claim activities as part of the Forest Service's Organic Act obligations."</p> <p>The court further rejected the agency's view that alternatives that greatly reduced environmental impacts to public land could be dismissed because they were too expensive for the company. "As discussed throughout this Order, the administrative record before the Forest Service reflects that Rosemont did not have valid surface rights for thousands of acres of its unpatented mining claims. Thus, rather than summarily rejecting this claim as 'technically and financially infeasible,' further consideration and</p>		

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>evaluation of this alternative was warranted as it greatly reduced the impacts to the Coronado National Forest.”</p> <p>Thus, at Stibnite, the Forest Service must fully comply with all federal laws and is not constrained by the limits in Part 228. Nor is the agency limited in its duties to protect public resources by Perpetua’s assertions of financial need or costs.</p> <p>Here, as at Rosemont, unless all the operations are proposed on verified valid claims, the operations are not “authorized by the mining laws” and the Forest Service must regulate the project under its Part 251/261 special use regulations, as well as FLPMA’s ROW provisions (discussed herein), and not under the Part 228 regulations. The agency’s authority under the Part 251 regulations are very different from, and much more environmentally protective, than the Part 228 regulations. For example, the agency must deny the project if “[t]he proposed use would not be in the public interest.” 36 C.F.R. § 251.54(e)(5)(ii).</p> <p>In contrast [to the Part 228A regulations], the Forest Service’s Part 251 regulations apply to “all uses of National Forest System lands, improvements, and resources.” 36 C.F.R. § 251.50. Any use not regulated under the Part 228, or several other groups of Forest Service regulations, falls into the Part 251 special use regulations. See id. These regulations provide a dual screening process in which the Forest Service may deny any activity that does not meet several standards or otherwise comport with the public interest. See id. § 251.54(e). The Part 251 regulations provide significant authority and discretion to prohibit activity on Forest Service lands, whereas the Part 228 regulations merely balance competing interests.</p> <p>The Part 251 regulations apply to occupancy and use of National Forest System lands. 36 C.F.R. §§ 251.54–251.64. The applicant must file a special use proposal with the District Ranger or Forest Supervisor having jurisdiction over the affected land. Id. § 251.54(b). The Forest Service conducts an initial screening to determine whether the proposed use meets the “minimum requirements applicable to all special uses.” Id. § 251.54(e)(1). If the proposal passes this initial screening, the Forest Service conducts a second-level screening which requires, among other things, a showing that the proposed use is in the public interest. Id. § 251.54(e)(5)(i)–(v). If the proposed use satisfies the Forest Service’s screening criteria, the Forest Service may grant a special use permit, but must include terms and conditions to “[m]inimize damage to scenic and esthetic values and fish and wildlife habitat and otherwise protect the environment,” among other requirements. Id. § 251.56(a)(1)(i)(B). The Forest Service must also “[o]therwise protect the public interest.” Id. § 251.56(a)(1)(ii)(G). In addition, under the related Part 261 regulations, the Forest Service is required to prohibit the destruction of cultural resources on public lands. See 36 C.F.R. §§ 261.9(g)-(h), 261.10(a), (b).</p> <p>(a) General. (1) Each special use authorization must contain:</p> <p>(i) Terms and conditions which will:</p> <p>(A) Carry out the purposes of applicable statutes and rules and regulations issued thereunder;</p> <p>(B) Minimize damage to scenic and esthetic values and fish and wildlife habitat and otherwise protect the environment;</p> <p>(C) Require compliance with applicable air and water quality standards established by or pursuant to applicable Federal or State law; and</p> <p>(D) Require compliance with State standards for public health and safety, environmental protection, and siting, construction, operation, and maintenance if those standards are more stringent than applicable Federal standards.</p> <p>(ii) Such terms and conditions as the authorized officer deems necessary to:</p> <p>(A) Protect Federal property and economic interests;</p> <p>(B) Manage efficiently the lands subject to the use and adjacent thereto;</p> <p>(C) Protect other lawful users of the lands adjacent to or occupied by such use;</p> <p>(D) Protect lives and property;</p> <p>(E) Protect the interests of individuals living in the general area of the use who rely on the fish, wildlife, and other biotic resources of the area for subsistence purposes;</p> <p>(F) Require siting to cause the least damage to the environment, taking into consideration feasibility and</p>		

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>other relevant factors; and (G) Otherwise protect the public interest. Id. § 251.56.</p> <p>These regulations also require the payment of fair market value for the use of the public’s land: “(a) ...special use authorizations shall require the payment in advance of an annual rental fee as determined by the authorized officer. (1) The fee shall be based on the fair market value of the rights and privileges authorized, as determined by appraisal or other sound business management principles.” Id. § 251.57.</p> <p>Because the Forest Service makes the same errors here as it did at Rosemont, the agency must reject the revised Plan of Operations submitted by Perpetua as inadequate and incomplete. The Forest Service must regulate the project under the correct legal regime. Further, the Forest Service has not shown that the project would meet all the requirements in Parts 251/261 to protect the public interest and the natural and cultural resources at/around the site. As such, the Forest Service must deny the proposed uses of public land.</p>		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	13	<p>A. A new Surface Use Determination is necessary to assess whether Perpetua Resources even has the right to use and occupy unpatented mining claims associated with the Stibnite Gold Project.</p> <p>In February 2020, a Surface Use Determination (SUD) was conducted for the Stibnite Gold Project (SGP) to: inform the authorized officer as to whether the proposed operational elements of the 2016 Stibnite Gold Project Plan of Operations proposed by Midas Gold, Inc. within Idaho Roadless areas are reasonably incident to mining and support the logical and sequential development of their mineral resource. SUD, p.1. A SUD should be conducted “[i]f questions arise about the logical sequence of a proposed or existing activity, or whether the activity is reasonably incident” to mining operations authorized by the United States mining laws. See FSM 2817.03a; see also 36 C.F.R. § 228.1. Moreover, as stated elsewhere in this letter, the Forest Service may not assume that unpatented mining claims are valid before regulating mining activities solely under the 36 C.F.R. Part 228A mining regulations. <i>Ctr. for Biological Diversity v. United States Fish & Wildlife Serv.</i>, 33 F.4th 1202, 1221 (9th Cir. 2022). Although Perpetua Resources Corp., through its subsidiary Idaho Gold Resources, LLC, holds nearly 1500 unpatented lode and millsite claims within the “operations boundary” and along the proposed Burntlog Route, there is nothing in the record that indicates any of these claims—especially those where use and occupancy will occur because of proposed mining activities—meet the statutory requirements of the United States mining laws. Because this and several other questions either have arisen or remain since the 2020 SUD, the Forest Service should conduct a new SUD to determine whether proposed activities are “reasonably incident mining uses.” Id. at 1222 (wondering whether permanent occupancy of invalid mining claims is a reasonably incident use). Furthermore, the SUD should be made available prior to any future NEPA milestones. B. Unpatented millsite claims in the vicinity of the TSF. When the Forest Service conducted the SUD in 2020, Perpetua Resources held a block of unpatented lode claims in the upper Meadow Creek drainage. These claims would have been buried beneath mine tailings as well as the TSF buttress dam. Compare SUD, at 37, Figure 7, with SUD, at 33, Figure 2. Additionally, a subsidiary of Perpetua Resources Corp. holds a block of 16 patented millsite claims (80-acres) where the Spent Ore Disposal Area/Bradley tailings are located. On September 1, 2022, Perpetua Resources abandoned a group of approximately 50 unpatented lode claims located to the west and south of these patented millsite claims (in the upper Meadow Creek drainage). That same day, Perpetua Resources filed 187 unpatented millsite claims in the same area as the just described abandoned unpatented lode claims. Commenters have provided the following map to illustrate where these new millsite claims are located in relation to historic and proposed mining claims and features. See Figure 1 and 2 below. Under the United States mining laws, millsite claims associated with a “vein or lode” must be located on “nonmineral land not contiguous to the vein or lode” and may not exceed five acres in size. 30 U.S.C. § 42(a). Additionally, the number of millsites a claimant can locate may be dependent upon the number of “associated” mining claims that meet the patenting requirements to ensure a one-to-one ratio between the two types of claims. Accordingly, if there are 188 unpatented mill site claims that were located and filed with BLM on September 1, 2022, there should also be 188 unpatented lode claims that meet the requirements necessary for patent, i.e., the claims must be valid because a discovery has occurred within the boundaries of the claim. See 30 U.S.C. §§ 26 and 29; see also <i>United States v. Cameron</i>, 252 U.S.</p>	REG	<p>The evidence being used by the Forest Service regarding the validity of the patented and unpatented mining claims is contained in Section 4 and Appendix II of the NI 43-101 Feasibility Study Technical Report (M3, 2021) which is part of the Project Record. This is discussed further in the prior response to Comment 17634-12. Based on this information, Forest Service has concluded that the SGP is pursuant to, and authorized by, the 1872 Mining Law. The Forest Service will also review the legitimacy of any mining claims filed since the Feasibility Study was released but believes the history and record of managing mining claims by Perpetua indicates that it is reasonably foreseeable that new mining claims would be established and maintained according to the requirements of the 1872 Mining Law.</p> <p>The Forest Service does not agree with the comment that removing and reprocessing or reusing the SODA material and Bradley tailings indicates the presence of mineralized land in conflict with controlling the land via millsite claims. In fact, these materials are clearly mining wastes produced by prior, legacy mining operations that currently present environmental impacts on federal land. Removing and relocating these wastes to the proposed TSF would clear these sources of environmental impacts from the underlying unmineralized land.</p> <p>The Forest Service intends to oversee the use of proposed borrow pits intended for construction of the Burntlog Route in compliance with 36 CFR 228.62(d). The details of said borrow pits would be provided to the Forest Service in the future. The overall disturbance area and environmental effects of these borrow sites is included in the SDEIS.</p>

			<p>450, 460 (1920) (“All must conform to the law under which [mining claim patents] are initiated; otherwise they work an unlawful private appropriation in derogation of the rights of the public.”). Because it appears that the mineral resources proposed to be mined for the SGP are located almost entirely on private lands, it is unclear whether there are 188 valid unpatented mining claims associated with the mineral resource. See Brown & Caldwell, Final Development Rock Management Plan 1-4 (May 2022) (depicting location of mineral resources at the proposed SGP mine site). Indeed, the SDEIS provides no documentation regarding specific mining claim locations and validity thereof nor has the Forest Service responded to requests for such documentation of specific claim locations and validity thereof. It also appears that at least 15 of the new millsite claims are located on top of an area that is proposed to be “re-mined” under the 2021 MMP. See Figure 1 and 2 below. See also Brown & Caldwell, Final Development Rock Management 4-5 (May 2022) (describing “plans to re-mine and reprocess the Bradley tailings deposited in the Meadow Creek Valley located within the planned footprint of the proposed TSF.... Other legacy materials that constitute tailings from pre-Bradley milling operations are likely present and commingled with the Bradley era materials in the area beneath the SODA as well as in adjacent areas”); Id. at 5-2 (map depicting core holes west of the SODA and Bradley tailings on National Forest lands). Because the plan to “re-mine” this area indicates the presence of mineralized land beneath the 15 (and perhaps more) millsite claims, the mill sites do not qualify as “nonmineral land” under the United States mining laws. Millsites identified as potentially being over-filed on land that is not “nonmineral” are: TSF-A-157; TSF-A-144; TSF-A-126; TSF-A-125; TSF-A-124; TSF-A-123; TSF-D-1; TSF-D-2; TSF-D-3; TSF-D-4; TSF-C-1; TSF-C-2; TSF-C-3; TSF-C-4; TSF-B-2. This list is not exhaustive. Depending on the extent of “re-mining” that occurs in this area, other millsite claims may overlay mineralized land. In any event, the Forest Service must determine whether the millsites are valid. These comments also incorporate by reference the map depicting locations of the newly filed unpatented mill site claims in relation to other mine site features—which is similar to maps in Figures 1 and 2 below—that is included on page 12 of the comments from the Nez Perce Tribe. Furthermore, the Forest Service’s “story map” for the original 2020 DEIS indicates that the area where Perpetua has filed the new millsite claims includes the Bradley Tailings, which are proposed to be “re-mined. In sum, the Forest Service must verify the validity of each unpatented lode and millsite claim within the operations boundary as well as along the proposed Burntlog Route where operations authorized by the United States mining laws are proposed to occur — whether or not the proposed operations’ use and occupancy of those claims is temporary or permanent.</p> <p>C. Unpatented lode claims located along the proposed Burntlog Route. Perpetua Resources Corp.’s subsidiaries have located unpatented lode mining claims along portions of the Burntlog Route between Trapper Creek and the larger claim block comprising the SGP project area. See Midas Gold PRO, Appendix C-4 (2016). With respect to these claims, if they will be used or occupied, whether temporarily or permanently, for activities reasonably incident to mining, they must be valid. Absent evidence supporting validity, their use and occupancy may not be permitted solely under 36 C.F.R. Part 228A. See <i>Ctr. for Biological Diversity v. United States Fish & Wildlife Serv.</i>, 33 F.4th 1202 (9th Cir. 2022). Here, validity is a critical determination because only “mining activities conducted pursuant to the General Mining Law of 1872” remain unaffected by the Idaho Roadless Rule. See 36 C.F.R. § 294.25(b). In other words, if mining activities are not conducted pursuant to the General Mining Law of 1872, the Idaho Roadless Rule restrictions fully apply. Use of lands not covered by valid claims under the Mining Law, are not “authorized by the mining laws.” See <i>Ctr. for Biological Diversity v. United States Fish & Wildlife Serv.</i>, 33 F.4th 1202 (9th Cir. 2022). Thus, in this case, for the Burntlog Route, the agency can only consider approval under the right-of-way (ROW) provisions of Title V of FLPMA (43 U.S.C. §§ 1761-1771) and its implementing regulations. As noted herein and in previous comments, due to the significant adverse impacts to environmental and cultural resources, and Treaty Rights, the project, including the Burntlog Route, does not qualify as an acceptable ROW. In addition, the Idaho Roadless Area themes along the Burntlog Route are designated Backcountry/ Restoration and Special Areas of Historic or Tribal Significance. Under the Rule, “the Forest Service will not authorize sale or use common variety mineral materials in Special Areas.” 36 C.F.R. § 294.25(c)(2). Thus, borrow pits to support construction and maintenance of the proposed Burntlog Route must not be sited in these areas whatsoever. Similarly, the Forest Service “may authorize the use and sale of common variety mineral</p>		

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>materials... only if the use of these mineral materials is incidental to an activity otherwise permissible in backcountry/restoration” areas. 36 C.F.R. § 294.25(d)(2). As such, the Rule limits road construction and reconstruction in these areas only to a narrow set of circumstances, which includes, among other things, roads “needed pursuant to... outstanding rights, or other legal duty of the United States. See 36 C.F.R. § 294.23(b)(1). None of these circumstances apply to the SGP if Perpetua’s mining operations are not pursuant to, i.e., “authorized by,” the General Mining Law of 1872. The Rule also allows “[t]emporary road construction or road reconstruction to reduce hazardous fuel conditions” within community protection zones or outside of community protection zones provided certain conditions exist. 36 C.F.R. §§ 294.23(b)(2) and (3); see also Jayne v. Sherman, 707 F.3d 944, 997 (9th Cir. 2013). Again, none of these conditions are satisfied unless the SGP is a mining activity pursuant to the General Mining Law of 1872. Notably, the SDEIS treats the road profile as a “permanent” total soil resource commitment because the roadbed would never move. SDEIS, at 4-82. Additionally, permanent features such as soil nails and cut and fill material would remain on the landscape indefinitely. Thus, regulating this type of permanent use and occupancy of unpatented mining claims along the Burntlog Route solely under 36 C.F.R. Part 228A requires that the claims on which the use and occupancy occur be valid. Even if a permit that authorizes mining activities is issued under another regulatory framework—such as 36 C.F.R. Part 251/61—the Burntlog Route would not be “needed” because other options exist to access the SGP. Indeed, a miner’s preferred means of access to mining claims has never been a right, i.e., “needed,” under the United States mining laws. See Clouser v. Espy, 42 F.3d 1522 (9th Cir. 1994). D. Proposed borrow pits along the Burntlog Route may not be permitted as “free use.” The 2020 Surface Use Determination claims that borrow sites along the Burntlog Route would be established “as needed,” and permitted under 36 C.F.R. § 228.62(d) and 16 U.S.C. § 477. SUD, at 12 n.8. Although free-use permits may be issued for mineral materials to miners, if the miner “owns or controls an adequate supply of mineral material in the area of demand,” the permit cannot be issued. 36 C.F.R. § 228.62(d). In addition, the volume of mineral materials removed by a corporation or individual cannot exceed “5,000 cubic yards (or weight equivalent) during any period of 12 consecutive months.” 36 C.F.R. § 228.62(d)(2). Accordingly, the Forest Service cannot issue free use permits if materials necessary for the construction and maintenance of the proposed Burntlog Route exceed this amount. Rather, the Forest Service must authorize such use under a different regulatory framework that is consistent with the United States mining laws governing disposal of common variety minerals. See 36 C.F.R. § 228.59(e)(1); see also 16 U.S.C. § 477 (Forest Service “may permit” use of sand and gravel by miners subject to regulations prescribed by the Secretary). The SDEIS must include a determination of the volume (or weight equivalent) of common varieties minerals that would be excavated annually from each proposed borrow pit along the proposed Burntlog Route, and must determine and disclose whether Perpetua’s proposed borrow pits qualify for “free use” permits. E. Validity of unpatented lode claims within the project boundary must be determined. Other landscape features associated with SGP mining activities, such as the fish tunnel, waste rock piles, portions of the tailing storage facility, and other landscape features, may permanently occupy unpatented lode mining claims. The Forest Service must determine whether each proposed mining operation that would occur on each unpatented lode claim held by Perpetua Resources is authorized by the United States mining laws. If the Forest Service determines these mining operations are not authorized by the United States mining law, it must regulate the project under the correct regulatory regime, which may require altering the scale, intensity, and/or scope of the SGP—even if that means a substantial reduction in the amount of mining waste that can be stored on national forest lands.</p>		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	14	<p>IV. THE PROJECT FAILS TO COMPLY WITH REQUIREMENTS FOR SPECIAL USES ON FEDERAL LANDS AND RIGHTS OF WAY UNDER FLPMA TITLE V</p> <p>Like with the other facilities proposed on the federal lands, the Forest Service is under the mistaken belief that the access/support corridors and uses thereof are subject only to the Part 228A regulations. The DEIS stated that: “transportation and utility uses associated with mineral development activities are authorized under 36 CFR 228A as part of an operator’s plan of operations and do not require a separate special use permit.” DEIS at 3.15-7. As noted above and herein, that is wrong. For the corridors, the DEIS failed to meet the strict public interest, environmental protection, and financial requirements of the Federal Land Policy and Management Act (FLPMA).</p>	REG	<p>As described in Section 2.4.4.7 of the SDEIS the electric utility line service for the SGP would be rebuilt or constructed by Idaho Power Company. Much of this work would occur on corridors already controlled by IPCo and some new or rerouted transmission lines would be located on right of ways or easements obtained by IPCo separately from Perpetua. As part of the SGP, the environmental effects of this utility work have been included in the SDEIS, but the land acquisition aspects of this work would be done by IPCo.</p> <p>The Burntlog Route access road is solely proposed to provide a year-round surface access route to the SGP which is a mining operation authorized under the 1872 Mining Law and regulated under the 36 CFR 228 Subpart A rules. The definition of mining "<i>operations</i>" in 36</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>The SDEIS modified this slightly, but does not specify which regulatory provisions actually apply – leaving the public in the dark: The action alternatives would require new ROWs or easements to accommodate the construction of new and upgraded access roads and transmission lines. These impacts would be located on private, state, and NFS lands; new transmission line ROW would not cross any Bureau of Reclamation lands for either action alternative. New ROWs on NFS lands are considered a direct effect to land use and may be authorized under Forest Service special uses regulations at 36 CFR 251 or under 36 CFR 228A depending on the type of use, location, and other factors. For purposes of this environmental analysis, the agency is assuming the proposed uses would be able to be authorized under existing regulatory authorities. However, the agency will need to evaluate the eventual applications for rights of way to make a final determination.</p> <p>Yet, as noted above, unless the proposed transmission lines, access roads, and other crossings of federal land are authorized by the Mining Law on valid claims, these uses are regulated under FLPMA, not under any assumed “rights” under the Mining Law.</p> <p>Under FLPMA Title V, Section 504 (which applies to both the Forest Service and BLM), the Forest Service may grant a ROW only if it “(4) will do no unnecessary damage to the environment.” 43 U.S.C. § 1764(a). Rights of way “shall be granted, issued or renewed . . . consistent with... any other applicable laws.” Id. § 1764(c). A right-of-way that “may have significant impact on the environment” requires submission of a plan of construction, operation, and rehabilitation of the right-of-way. Id. § 1764(d). A Title V SUP/ROW “shall contain terms and conditions which will... (ii) minimize damage to scenic and esthetic values and fish and wildlife habitat and otherwise protect the environment.” Id. § 1765(a).</p> <p>In addition, the ROW can only be issued if activities resulting from the ROW:</p> <p>(i) protect Federal property and economic interests; (ii) manage efficiently the lands which are subject to the right-of-way or adjacent thereto and protect the other lawful users of the lands adjacent to or traversed by such right-of-way; (iii) protect lives and property; (iv) protect the interests of individuals living in the general area traversed by the right-of-way who rely on the fish, wildlife, and other biotic resources of the area for subsistence purposes; (v) require location of the right-of-way along a route that will cause least damage to the environment, taking into consideration feasibility and other relevant factors; and (vi) otherwise protect the public interest in the lands traversed by the right-of-way or adjacent thereto. Id. § 1765(b).</p> <p>At least three important potential substantive requirements flow from the FLPMA’s ROW provisions. First, the Forest Service has a mandatory duty under Section 505(a) to impose conditions that “will minimize damage to scenic and esthetic values and fish and wildlife habitat and otherwise protect the environment.” Id. § 1765(a). The terms of this section do not limit “damage” specifically to the land within the ROW corridor. Rather, the repeated use of the expansive term “the environment” indicates that the overall effects of the ROW on cultural/historical, wildlife, environmental, scenic and aesthetic values must be evaluated and these resources protected. In addition, the obligation to impose terms and conditions that “protect Federal property and economic interests” in Section 505(b) requires that the Forest Service must impose conditions that protect not only the land crossed by the right-of-way, but all federal land affected by the approval of the ROW. This includes the federal waters and water rights that will be eliminated or significantly reduced by the project.</p> <p>The requirements in Section 505(b) mandate a Forest Service determination as to what conditions are “necessary” to protect federal property and economic interests, as well as “otherwise protect[ing] the public interest in the lands traversed by the right-of-way or adjacent thereto.” (emphasis added). This means that the agency can only approve the ROW if it “protects the public interest in lands” not only upon which the road would traverse, but also lands and resources adjacent to and associated with the ROW. As noted herein, the Forest Service would be unable to make a legitimate finding that industrial use of the lands served by the ROW, given the massive adverse impacts from the Mine, would “protect the public interest.”</p> <p>Third, is the requirement that the right-of-way grants “do no unnecessary damage to the environment” and be “consistent with . . . any other applicable laws.” Id. §§ 1764(a)-(c). This means that a grant of a</p>		<p>CFR 228.3(a) includes "<i>mining or processing of mineral resources and all uses reasonably incident thereto, including roads and other means of access on lands subject to the regulations of this part, regardless of whether said operations take place on or off mining claims.</i>" The Forest Service believes the proposed Burntlog Route would be correctly regulated under the 228 Subpart A regulations and not the 36 CFR 251 rules.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>ROW supporting other activities must satisfy all applicable treaties and laws, regulations and policies, including FLPMA, the Endangered Species Act (ESA), Organic Act, the National Forest Management Act (NFMA), National Historic Preservation Act (NHPA), Clean Water and Air Acts (CWA, CAA), all state and local laws, etc.</p> <p>Federal courts have repeatedly held that the federal land agency not only has the authority to consider the adverse impacts on lands and waters outside the immediate ROW corridor, it has an obligation to protect these resources under FLPMA. In <i>County of Okanogan v. National Marine Fisheries Service</i>, the court affirmed the Forest Service’s imposition of mandatory minimum stream flows as a condition of granting a ROW for a water pipeline across Forest Service land.²² This was true even when the conditions/requirements restricted or denied vested property rights (in that case, water rights). The Forest Service thus cannot issue a ROW that fails to “protect the environment” required by FLPMA, including the environmental resource values in and out of the ROW corridor. “FLPMA itself does not authorize the Supervisor’s consideration of the interests of private facility owners as weighed against environmental interests such as protection of fish and wildlife habitat. FLPMA requires all land-use authorizations to contain terms and conditions which will protect resources and the environment.”</p> <p>The Interior Department, interpreting FLPMA Title V and its right-of-way regulations, has held that: “A right-of-way application may be denied, however, if the authorized officer determines that the grant of the proposed right-of-way would be inconsistent with the purpose for which the public lands are managed or if the grant of the proposed right-of-way would not be in the public interest or would be inconsistent with applicable laws.”</p> <p>Similar to the <i>County of Okanogan</i> and <i>Colorado Trout Unlimited</i> federal court decisions noted above, the Interior Department has held that the fact that a ROW applicant has a property right that may be adversely affected by the denial of the ROW does not override the agency’s duties to protect the “public interest.” In <i>Kenneth Knight</i>, the BLM’s denial of the ROW was affirmed due not only to the direct impact of the water pipeline, but on the adverse effects of the removal of the water in the first place:</p> <p>[T]he granting of the right-of-way and concomitant reduction of that resource, would, in all likelihood, adversely affect public land values, including grazing, wildlife, and riparian vegetation and wildlife habitat. The record is clear that, while construction of the improvements associated with the proposed right-of-way would have minimal immediate physical impact on the public lands, the effect of removal of water from those lands would be environmental degradation. Prevention of that degradation, by itself, justified BLM’s rejection of the application.</p> <p>That was also the case in <i>Clifford Bryden</i>, as the adverse impacts from the removal of the water was considered just as important as the adverse impacts from the pipeline that would deliver the water.</p> <p>In <i>King’s Meadow Ranches</i>, the Interior Board of Land Appeals (IBLA) affirmed the denial of right-of-way for a water pipeline, where the pipeline would degrade riparian vegetation and reduce bald eagle habitat. The Department specifically noted that under FLPMA Title V: “[A]s BLM has held, it is not private interests but the public interest that must be served by the issuance of a right-of-way.” As the IBLA recently held: The public interest determination is more than a finding that no laws will be violated by granting the ROW. Even if UUD [Unnecessary or Undue Degradation] can be avoided, degradation to public resources posed by a requested ROW may factor into BLM’s determination of whether that ROW would be in the public interest. For example, in <i>Sun Studs</i>, we upheld BLM’s rejection of a logging road ROW permit based on environmental considerations without any suggestion that the environmental harm rose to the level of unlawful degradation.</p> <p>The Interior Department has ruled that pipelines and associated infrastructure, including those across public land related to a mining operation, are not covered by statutory rights under the Mining Law. “[A] right-of-way must be obtained prior to transportation of water across Federal lands for mining.” Although these cases dealt with BLM lands, they apply equally to Forest Service lands. As noted in <i>Alanco</i>, ROWs for access roads (as opposed to internal mine roads) are subject to FLPMA’s Title V requirements.</p>		

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>The IBLA has expressly rejected the argument that rights under the mining laws apply to pipelines and roads associated with water delivery:</p> <p>Clearly, FLPMA repealed or amended previous acts and Title V now requires that BLM approve a right-of-way application prior to the transportation of water across public land for mining purposes. See 43 U.S.C. § 1761 (1982). As was the case prior to passage of Title V of FLPMA, however, approval of such an application remains a discretionary matter and the Secretary has broad discretion regarding the amount of information he may require from an applicant for a right-of-way grant prior to accepting the application for consideration. <i>Bumble Bee Seafoods, Inc.</i>, 65 IBLA 391 (1982). A decision approving a right-of-way application must be made upon a reasoned analysis of the factors involved in the right-of-way, with due regard for the public interest. See <i>East Canyon Irrigation Co.</i>, 47 IBLA 155 (1980). BLM apparently contends that a mining claimant does not need a right-of-way to convey water from land outside the claim for use on the claim. It asserts that such use is encompassed in the implied rights of access which a mining claimant possesses under the mining laws. Such an assertion cannot be credited.</p> <p>The implied right of access to mining claims never embraced the right to convey water from outside the claim for use on the claim. This latter right emanated from an express statutory grant in the 1866 mining act. See 30 U.S.C. § 51 (1970) and 43 U.S.C. § 661 (1970). In enacting FLPMA, Congress repealed the 1866 grant of a right-of-way for the construction of ditches and canals (see § 706(a) of FLPMA, 90 Stat. 2793) and provided, in section 501(a)(1), 43 U.S.C. § 1761(a)(1), for the grant of a right-of-way for the conveyance of water under new procedures. In effect, Congress substituted one statutory procedure for another. There is simply no authority for the assertion that mining claimants need not obtain a right-of-way under Title V for conveyance of water from lands outside the claim onto the claim.</p> <p>The same analysis applies to transmission lines, pipelines, etc., delivering or transporting power, water, water, tailings, etc., on federal land. The leading treatise on federal natural resources law confirms this rule: “Rights-of-way must be explicitly applied for and granted; approvals of mining plans or other operational plans do not implicitly confer a right-of-way.”</p> <p>The fact that the Forest Service mining regulations consider roads and pipelines associated with the project part of the mineral “operations,” 36 CFR § 228.3, does not override these holdings or somehow create statutory rights where none exist.</p> <p>[I]t does not follow that the Forest Service must use these Part 228 regulations merely because an action falls within the regulation’s definition of operations. The Forest Service’s reliance on its definition of operations ignores the purpose of its own regulations. Part 228 regulates “use of the surface of National Forest System lands in connection with operations authorized by the United States mining laws (30 U.S.C. 21-54 [Mining Law of 1872]).” 36 C.F.R. § 228.1. Therefore, authorization under the Mining Law of 1872 acts as a precursor to any regulation through Part 228.</p> <p>Further, “Access to patented mining claims, mineral leases, and private property inholdings are not subject to 36 CFR part 228, subpart A nor to the access provisions as discussed herein.” U.S. Forest Service Minerals Manual § 2817.25.</p> <p>Overall, the SDEIS and agency review of these facilities fails to apply the proper discretionary and public interest review applicable to Title V and its implementing regulations. This failure, as well as the fundamental errors in assuming that Perpetua has a statutory right to receive approval of any delivery, conveyance, transmission, or access facilities, further undermines the agencies’ NEPA alternatives and mitigation analysis.</p> <p>Lastly, the Forest Service failed to comply with the financial requirements of FLPMA regarding ROW applications and approvals. At a minimum, the Forest Service must obtain “Fair Market Value” (FMV) for the use of federal land and resources. FLPMA requires that “the United States receive fair market value of the use of the public lands and their resources.” 43 U.S.C. § 1701(a)(9). “The holder of a right-of-way shall pay in advance the fair market value thereof, as determined by the Secretary granting, issuing, or renewing such right-of-way.” 43 U.S.C. § 1764(g). In addition, Perpetua must fully</p>		

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			“reimburse the United States for all reasonable administrative and other costs incurred in processing an application for such right-of-way and in inspection and monitoring of such construction, operation, and termination of the facility pursuant to such right-of-way.” Id. Forest Service regulations state that: “(a) ...special use authorizations shall require the payment in advance of an annual rental fee as determined by the authorized officer. (1) The fee shall be based on the fair market value of the rights and privileges authorized, as determined by appraisal or other sound business management principles.” 36 C.F.R. § 251.57.		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	21	Since the DEIS, Perpetua has abandoned some mining claims and submitted new mining claims, as discussed already. The Forest Service cannot simply assume the claims are valid, the claims cover the proposed activities, and that the Stibnite Gold Project will have the same effects as it would have previously under the different configuration of claims.	REG	<p>The Forest Service is not assuming the validity of the mining claims included in the SGP. The status of the mining claims for the area of the SGP is described in Section 4 and Appendix II of the 2021 Feasibility Study Technical Report which was prepared in compliance with the National Instrument 43-101 of the Canadian Securities Administrators Standards (NI 43-101) for reporting mineral properties (M3, 2021). The purpose of NI 43-101 is to ensure that misleading or erroneous information on mineral properties is not published or represented to potential investors on the stock exchanges overseen by the Canadian Securities Authority. A 43-101 feasibility study is a comprehensive technical and economic description of a mineral project prepared by experts who must have the prerequisite qualifications ("Qualified Persons").</p> <p>Section 4 of the Feasibility Study describes the mineral title of the SGP property in some detail. It references a legal opinion prepared by a well-known law firm with expertise in these matters, Parson, Behle & Latimer. The report also states, "no significant flaws or title issues have been identified in multiple formal title reviews of the claims performed by qualified, independent, title examiners".</p> <p>This report describes the mineralization at the SGP property and the location of the mineral resources to be mined on patented and unpatented mining claims within the property. The report also states that, as of the effective date of the report, December 2020, the property taxes were paid in full for the patented mining claims. Maintenance of the unpatented mining claims requires that the BLM be provided with the serial numbers and evidence of maintenance fees of the claims on or before September 1 of each year. The report states that this was completed for the most recent filing year prior to release of the report on August 3, 2020 and that an Affidavit of Satisfaction was subsequently recorded with Valley County on August 20, 2020. This information can be considered reliable evidence that the subject claims are properly authorized by the 1872 Mining Law.</p> <p>The Feasibility Report was cited in the SDEIS and is part of the Project Record. The property ownership information of the report has been reviewed by the Forest Service and determined to be reliable.</p> <p>Based on the reliable property ownership description in the Feasibility Study Technical Report, the Forest Service believes the SGP is properly regulated under the 36 CFR Part 228 regulations.</p>
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	60	<p>VIII. FAILURE TO MINIMIZE ALL ADVERSE ENVIRONMENTAL IMPACTS AND TO PROTECT PUBLIC RESOURCES</p> <p>Even under the Forest Service’s erroneous decision to regulate the project solely through its Part 228A regulations, the agency failed to minimize all adverse impacts, as shown herein. Under the Organic Act and Part 228A regulations, the agency must “maintain and protect fisheries and wildlife which may be affected by the operations.” 36 C.F.R. § 228.8(e). These impacts also violate the Forest Service’s duties to “minimize adverse environmental impacts on National Forest surface resources.” 36 C.F.R. § 228.8. “The operator also has a separate regulatory obligation to ‘take all practicable measures to maintain and protect fisheries and wildlife habitat which may be affected by the operations.’ 36 C.F.R. § 228.8(e).” “Under the Organic Act the Forest Service must ...require [the project applicant] to take all practicable measures to maintain and protect fisheries and wildlife habitat.”</p>	REG	<p>The compliance with the regulations cited in the comment relating to minimizing adverse effects, and taking all practicable measures to maintain and protect fisheries and wildlife habitat are open to interpretation and judgment on a site-specific basis. The Forest Service believes that application of the existing regulatory and Forest Plan requirements identified in Table 2.4-12 along with the proponent proposed Design Features listed in Table 2.4-13 of the SDEIS show the intent of both parties to maintain and protect the fisheries and wildlife resources. The environmental effects descriptions for fisheries and wildlife contained in Sections 4.12 and 4.13 of the SDEIS describe the impacts to these resources and any mitigative measures that can be applied to avoid or reduce these impacts.</p>

			<p>The CWA, Organic Act, and agency regulations preclude the Forest Service from approving aspects of a mining operation that would violate federal or state water quality standards.</p> <p>Under the Clean Water Act Section 313, the Forest Service cannot authorize mining operations that do not comply with state and federal water quality regulations, including a state’s antidegradation policy. 33 U.S.C. § 1323(a).</p> <p>The Organic Act mandates the same compliance, as the Part 228 regulations “further require that mining operators comply with applicable state and federal water quality standards including the Clean Water Act; [and] take all practicable measures to maintain and protect fisheries and wildlife habitat.” The 228 regulations require that the operator submit sufficient information to enable the agency to ensure that the Project will comply with all applicable state and federal requirements to protect water quality and fisheries. See 36 C.F.R. §§ 228.4(c)(3), 228.8(b), 228.8(e). The SDEIS does not show, or properly analyze, that all aspects of the project will fully protect “fisheries and wildlife habitat.” This is in addition to the agency’s/project’s failure to fully protect all uses, including Treaty-reserved rights and resources.</p>		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	61	<p>Part 228 regulations are used, the Organic Act prevents the Forest Service from adversely affecting public waters, such as the waters and springs that will be adversely affected/eliminated by the project.</p> <p>This is also true for the critical wetlands, riparian areas, and Groundwater Dependent Ecosystems that will be severely impacted by the project. In addition to the Executive Order on Wetlands Protection (which requires the Forest Service to protect wetlands), the Organic Act requires the Forest Service to protect public land water resources, which has not been done.</p> <p>[N]ational forests...shall be as far as practicable controlled and administered in accordance with the following provisions. No national forest shall be established, except to improve and protect the forest within the boundaries, or for the purpose of securing favorable conditions of water flows, and to furnish a continuous supply of timber for the use and necessities of citizens of the United States. 16 U.S.C. §475.</p> <p>“The legislative debates surrounding the Organic Administration Act of 1897 and its predecessor bills demonstrate that Congress intended national forests to be reserved for only two purposes – ‘to conserve the water flows, and to furnish a continuous supply of timber for the people.”</p>	REG	<p>Impacts of the SGP on surface water and groundwater resources are described in Sections 4.8 and 4.9 of the SDEIS. Impacts to wetlands and riparian resources are described in Section 4.11. These sections also include descriptions of any mitigative measures proposed by the Forest Service to avoid or reduce certain of these impacts or their severity.</p> <p>The Purpose statement of the 36 CFR 228A regulations in 36 CFR 228.1 clearly states that National Forest System lands can be utilized in connection with operations authorized by United States mining laws. This is different than the statement made in the comment that Congress intended national forests to be reserved for only two purposes - "to conserve the water flows and to furnish a continuous supply of timber for the people".</p>
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	62	<p>“The objects for which the forest reservations should be made are the ... preservation of forest conditions upon which water conditions and flows are dependent.”</p> <p>New Mexico recognized that the “preservation” of conditions for water flow was aimed primarily at providing water for uses outside the forest boundaries – contradicting the agency’s position here that it has no authority over actions on the forests that may eliminate or impair off-forest resources. “Congress authorized the national forest system principally as a means of enhancing the quantity of water that would be available to the settlers of the arid West.” Yet instead of “enhancing” water supplies, the project will adversely affect water that would otherwise be available and in good quality for the Forest, to downstream water users, and under rights reserved and guaranteed to the Nez Perce Tribe by treaty.</p> <p>Although the Act itself and the New Mexico decision shows that the Forest Service’s abdication of authority here is invalid, this does not mean that mining is precluded whenever it affects downstream water supplies. “Congress intended the national forests to be put to a variety of uses ... not inconsistent with the two principal purposes of the forests.”</p> <p>Thus, the Forest Service failed to “preserv[e] forest conditions upon which water conditions and flows are dependent.” Here, the Forest Service never considered whether its approval of the Stibnite Gold Project is “consistent with” one of the “primary purposes” of the Payette National Forest – “enhancing” and “preserving” water conditions/flows. And based on the information that is provided in the SDEIS, the Stibnite Gold Project is not consistent with that purpose, as it will destroy, alter, and degrade wetlands and creeks throughout the mining area and along the transportation and utility routes.</p>	REG	<p>Section 4.8 of the SDEIS describes proposed changes to existing stream channels within the SGP operations area. Some of these changes would be temporary during operations and the channels would be restored during reclamation activities. Other changes would be permanent. One of the major changes is to the East Fork SFSR which currently flows through the Yellow Pine Pit that block fish passage upstream. This stream would be temporarily rerouted during operations around the enlarge open pit in a diversion tunnel designed to allow fish passage. The Yellow Pine Pit would then be backfilled and the stream restored across the backfill and a new in-stream lake to permanently restored fish passage through this reach.</p> <p>The existing Blowout Creek would not be impacted by the operations but would be reconstructed voluntarily to restore a stable and less erosive condition than is currently present.</p> <p>Meadow Creek would be diverted during operations and reconstructed during reclamation to a more natural channel and floodplain. There would be an artificial channel reach where the creek passes over the TSF embankment outer slope which would present a permanent barrier to upstream fish passage.</p> <p>The SDEIS states that surface water flow rates in affected streams would be lessened during parts of the mine operations but are not expected to be permanently impacted by the SGP and natural flow rates would be restored within about 10 years of cessation of operations.</p> <p>Section 4.9 of the SDEIS describes the water treatment plans for the SGP which would be driven largely by mine dewatering and contact runoff water from mine operations areas. The</p>

			<p>Regarding long-term impacts to public resources, the SDEIS admits that long-term or perpetual treatment of water pollution would be needed. SDEIS at 2-91. At the outset, the SDEIS admits that treatment issues have not been adequately considered in the DEIS: "Evaluation of post closure water treatment is ongoing." SDEIS at 2-91. This is the exact same statement from the first DEIS (at 2-75), yet the problem has not been resolved. The agency cannot proceed to issue a Final EIS without allowing the public to comment on final treatment issues in the SDEIS.</p>		<p>reclamation of tailings, pit backfills, and the largest development rock storage facility (buttress) includes placement of impermeable geosynthetic covers overlain by growth material. After this is accomplished the water treatment rate is predicted to decrease until treatment potentially can cease in mine year 40. Permanent treatment is not inevitable. The treatment effluent to site receiving streams would comply with the water quality standards for the streams. Water treatment processes are described in Section 4.9.2 to satisfy the understanding of reasonably foreseeable conditions.</p> <p>Section 4.11 of the SDEIS describes that more than 119 acres of wetlands in the mine site would be permanently filled. This section also states that compensatory mitigation of these impacted acres would ensure no net loss of wetland functions. The SDEIS also describes potential impacts to wetlands adjacent to mine operations or new/improved access roads including from pollutants and sediments delivered to receiving streams but that mitigation measures are expected to reduce these impacts.</p> <p>Section 4.12 of the SDEIS discusses impacts to fisheries. It states that long-term arsenic, antimony, and mercury concentrations in the West End Pit lake would be slightly exceed the strictest potentially applied water quality standards, which are for human consumption of the water and any fish in the water. However, the pit lake is not expected to be a drinking water source or overflow to surface water streams and would be fishless. Impacts of these contaminants in the pit lake were described in the SDEIS as minor, permanent and localized.</p>
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	63	<p>Allowing such perpetual pollution conditions to exist, including a permanently polluted pit lake, violates the Forest Service's duties to protect public resources, water quality, aquatic life, and wildlife. The Forest Service cannot approve any operations that will require long-term or perpetual treatment (e.g., mine water treatment). The potential for a financial assurance/bond to cover treatment of perpetual pollution (as noted in the SDEIS) does not satisfy the agency's obligation not to approve operations that would result in such conditions in the first place.</p> <p>Allowing an operation to begin that will admittedly never be fully reclaimed due to its unending need for perpetual treatment violates the Forest Service's duties to ensure the protection of public resources under the Organic Act, Minerals Policy Act of 1970, and other applicable laws. Although written for coal mines, there is no reason why the Forest Service cannot adopt this requirement for the Stibnite Gold Project in order to comply with the Organic Act, NFMA, CWA, etc.</p> <p>Under the Organic Act, NFMA, the CWA, 1970 Act, and the Part 228 regulations (as well as the Part 251/261 rules), the Forest Service cannot approve a mine that does not ensure that reclamation will be completed – i.e., a mine that will require perpetual treatment. Under the Part 228 regulations, the agency can only approve a mine that can be reclaimed. In detailing the reclamation requirements, the regulation states that the:</p> <p>[O]perator shall, where practicable, reclaim the surface disturbed in operations by taking such measures as will prevent or control onsite and off-site damage to the environment and forest surface resources including:</p> <ol style="list-style-type: none"> (1) Control of erosion and landslides; (2) Control of water runoff; (3) Isolation, removal or control of toxic materials; (4) Reshaping and revegetation of disturbed areas, where reasonably practicable; and (5) Rehabilitation of fisheries and wildlife habitat. <p>36 CFR § 228.8(g) (emphasis added). By allowing the continuation/creation of a mine with perpetual toxic/polluted waters, the agency has violated these requirements.</p> <p>As noted in the Forest Service's Anatomy of a Mine regulatory guidance report, reclamation is a critical and required component of a logical, complete and reasonable mining plan:</p>	REG	<p>The water chemistry of the West End Pit lake is predicted to be within compliance with potentially applicable water quality standards except for three parameters and the pollution caused by these is considered to be minor, permanent, and localized to the lake.</p> <p>The need for operation of onsite water treatment is predicted to decrease after mine operations cease until about mine year 40 when treatment might be able to be terminated.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>Satisfactory reclamation should emphasize three major objectives:</p> <ol style="list-style-type: none"> 1. The productivity of the reclaimed land should at least equal that of the premine surface. This does not necessarily mean that the site must be restored to an approximation of its original condition, or that surface uses after mining will be the same as those existing prior to mining. For example, an area used for marginal grazing prior to mining may be changed to a useful and attractive recreational complex, or perhaps in another case to a housing area. 2. Satisfactory reclamation should leave the mined area in a condition that will not contribute to environmental degradation either in the form of air- or water-borne materials, or from chemical pollution. 3. The reclaimed area should be aesthetically acceptable and it should be safe for the uses intended. <p>The Mining and Minerals Policy Act also mandates successful and final reclamation of mine operations approved by the Forest Service, requiring “the reclamation of mined land, so as to lessen any adverse impact of mineral extraction and processing upon the physical environment that may result from mining or mineral activities.” 30 U.S.C. § 21a. No such plan to “lessen any adverse impact” from the creation of the polluted waters has been proposed or required in this case.</p> <p>The creation of a perpetual source of contaminated water, especially one which is a direct threat to wildlife, violates the federal laws and regulations noted herein. As such, the Forest Service cannot issue a record of decision (ROD) that may involve such activities and must reject any plan of operations that does not prevent the mine water contamination. Furthermore, the Forest Service’s failure to fully review, and subject the review to public comment, these water quality treatment issues violates NEPA, as discussed below.</p>		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	77	<p>X. THE SDEIS FAILS TO ADEQUATELY EXPLAIN AND DEMONSTRATE HOW THE PROPOSED PROJECT WOULD COMPLY WITH THE ENDANGERED SPECIES ACT</p> <p>The Endangered Species Act (ESA) represents “the most comprehensive legislation for the preservation of endangered species ever enacted by any nation.” <i>Tennessee Valley Authority v. Hill</i>, 437 U.S. 153, 180 (1978). “The plain intent of Congress in enacting this statute was to halt and reverse the trend towards species extinction, whatever the cost.” <i>Tennessee Valley Authority</i>, 437 U.S. at 184. In enacting the ESA, Congress spoke “in the plainest of words, making it abundantly clear that the balance has been struck in affording endangered species the highest of priorities, thereby adopting a policy which it described as ‘institutionalized caution.’” <i>Id.</i> at 194.</p> <p>One would be hard pressed to find a statutory provision whose terms were any plainer than those in [Section] 7 of the Endangered Species Act.” <i>Tennessee Valley Authority</i>, 437 U.S. at 173. “It’s very words affirmatively command all federal agencies ‘to insure that actions authorized, funded, or carried out by them do not jeopardize the continued existence’ of an endangered species or ‘result in the destructions or modification of habitat of such species.’” <i>Id.</i>, (quoting 16 U.S.C. 1536) (emphasis in original). “This language admits of no exception. Pursuant to Section 7 of the ESA, each federal agency must consult with the United States Fish and Wildlife Service (FWS) and/or NOAA Fisheries to ensure that any proposed action is not likely to jeopardize the continued existence of any threatened or endangered species, or result in the destruction or adverse modification of the species’ critical habitat. 16 U.S.C. § 1536(a)(2). As recognized in the SDEIS, FWS “generally manages ESA-listed terrestrial and freshwater plant and animal species, while NOAA Fisheries is responsible for marine fisheries, including anadromous fish.” SDEIS, p. 3-263.</p> <p>During Section 7 consultation, the action agency, FWS, and NOAA Fisheries must use the best scientific data available. 16 U.S.C. § 1536(a)(2). If the proposed action “may affect” any listed species or critical habitat, the action agency must engage in “formal consultation” with FWS and/or NOAA Fisheries. 50 C.F.R. § 402.14(a). To complete formal consultation, FWS and/or NOAA Fisheries must provide the action agency with a “biological opinion” explaining how the proposed action will affect listed species and critical habitat. 16 U.S.C. § 1536(b)(3); 50 C.F.R. § 402.14(g)(3)-(4), (l)(1). The biological opinion must include the current status of the listed species, a detailed discussion of the “effects of the action” on</p>	REG	In compliance with the ESA, the PNF is preparing a Biological Assessment for submission to the USFWS and NOAA and this document will be available when the Final EIS is issued.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>listed species and critical habitat, and the expert agency’s conclusion as to whether the action is likely to jeopardize a listed species or adversely modify critical habitat.</p> <p>16 U.S.C. § 1536(b)(3)(A); 50 C.F.R. § 402.14(h); Wild Fish Conservancy v. Salazar, 628 F.3d 513, 518 (9th Cir. 2010).</p> <p>If FWS and/or NOAA Fisheries conclude that the action is likely to jeopardize the continued existence of a listed species, or result in the destruction or adverse modification of critical habitat, FWS and/or NOAA Fisheries must outline “reasonable and prudent alternatives” to the proposed action. 16 U.S.C. § 1536(b)(3)(A). If FWS and/or NOAA Fisheries conclude in the biological opinion that the action is not likely to jeopardize listed species, or destroy or adversely modify critical habitat, the expert agency must provide an “incidental take statement” with the biological opinion, specifying the extent of incidental takings of listed species, the “reasonable and prudent measures” considered necessary or appropriate to minimize such impact, and the “terms and conditions” that must be complied with to implement those measures. Id. § 1536(b)(4); 50 C.F.R. § 402.14(i). If at any time the anticipated amount of incidental taking is exceeded, the agencies must immediately reinitiate consultation. 50 C.F.R. § 401.14(i)(4); id. § 402.16(a).</p> <p>The ESA mandates that “federal agencies take no action that will result in the ‘destruction or adverse modification’ of designated critical habitat.” National Wildlife Federation v. National Marine Fisheries Service, 524 F.3d 917, 933 (9th Cir. 2007) (quoting 16 U.S.C. 1536(a)(2)). “Destruction or adverse modification” of critical habitat is defined as a direct or indirect alteration that appreciably diminishes the value of the critical habitat for the conservation of a listed species. 50 C.F.R. § 402.02. During the Section 7 consultation, the agencies must consider impacts that appreciably diminish the value of critical habitat for either the survival or recovery of the species. National Wildlife Federation v. National Marine Fisheries Service, 524 F.3d at 934; Gifford Pinchot Task Force v. U.S. Fish and Wildlife Service, 378 F.3d 1059, 1069-71 (9th Cir. 2004).</p> <p>Thus, the agencies’ assessment of the impacts of a proposed action on a listed species’ critical habitat during ESA consultation must include the project’s impact on the species’ habitat in terms of the species’ recovery as well as its survival, and how the action may impact the physical or biological features that were the basis for the species’ critical habitat determination. 50 C.F.R. § 402.02; National Wildlife Federation, 524 F.3d at 935; Gifford Pinchot, 378 F.3d at 1069. In addition, the agencies are not allowed to characterize as “insignificant” the potential impacts on a species’ critical habitat by considering only the broad scale or long-term impacts. National Wildlife Federation, 524 F.3d at 935; Gifford Pinchot, 378 F.3d at 1069.</p> <p>For the proposed Stibnite Gold Project, the Forest Service states that the following species have been included in informal consultation discussions based on suitable habitat and known occurrences in and around the Project:</p> <ul style="list-style-type: none"> • Canada Lynx (Federally Threatened) • Northern Idaho Ground Squirrel (Federally Threatened) • Wolverine (Proposed Threatened) • Killer whale (Federally Endangered) • Snake River Spring/Summer Chinook salmon (Federally Threatened with Designated Critical Habitat) • Snake River Basin Steelhead (Federally Threatened with Designated Critical Habitat) • Columbia River bull trout (Federally Threatened with Designated Critical Habitat) • Monarch Butterfly (Federal Candidate) • Whitebark Pine (Federally Threatened) <p>SDEIS, p. 6-4.</p> <p>In order to comply with Section 7 of the ESA, it is clear from the SDEIS and the proposed action that the Forest Service must engage in formal consultation with both FWS and NOAA Fisheries concerning the potential impacts to listed species, especially concerning the impacts to the federally threatened Chinook salmon, steelhead, bull trout, and their formally designated critical habitats.</p>		

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>The Forest Service acknowledges in the SDEIS that the federally threatened Chinook salmon, steelhead trout, and bull trout are known to be present in the analysis area. SDEIS, p. 3-266. NOAA Fisheries listed the Snake River spring/summer-run Chinook salmon Evolutionary Significant Unit as threatened under the ESA in 1992. Id. The Forest Service acknowledges that this threatened species is found throughout the analysis area, including the South Fork Salmon River subbasin. Id. Additionally, designated critical habitat for Chinook salmon “includes all presently and historically accessible rivers and streams within the analysis area, except for the Payette River drainage.” Id., p. 3-270. The Forest Service further acknowledges that Chinook salmon and its designated critical habitat would be adversely affected by the proposed action. Id., pp. 4-357 - 4-366.</p> <p>NOAA Fisheries listed the Snake River Basin Steelhead Distinct Population Segment as threatened in 1997. SDEIS, p. 3-280. The threatened steelhead is found in the East Fork, South Fork Salmon River drainage and its tributaries downstream of the Yellow Pine pit lake. Id. NOAA Fisheries has also designated critical habitat for Snake River Basin steelhead throughout much of the analysis area, including the East Fork, South Fork Salmon River drainage to approximately 0.4 km upstream of the confluence with Sugar Creek. Id. The Forest Service recognizes that the proposed action would adversely affect steelhead, including its critical habitat. Id., pp. 4-366 – 4-373.</p> <p>FWS listed the Columbia River Distinct Population Segment of bull trout in 1998. SDEIS, p. 3-286. Bull trout are currently known to use spawning and rearing habitat in at least 28 streams within the South Fork Salmon River subbasin. Id. FWS also designated critical habitat for bull trout throughout the South Fork Salmon watershed, including the East Fork, South Fork Salmon River. Id. The Forest Service acknowledges that the proposed action would adversely affect bull trout, including its critical habitat. Id., pp. 4-373 – 4-379.</p> <p>Based on the Forest Service’s analysis and acknowledgments within the SDEIS, the Forest Service, FWS, and NOAA Fisheries must formally consult on the adverse impacts of the proposed action on threatened fish and their designated critical habitat in the analysis area in order to comply with Section 7 of the ESA. 16 U.S.C. § 1536(a)(2). This formal consultation must result in either reasonable and prudent alternatives, if jeopardy or adverse modification is found to be likely, or an incidental take statement that fully satisfies the requirements of the ESA. Moreover, during the consultation process and within the Biological Opinion, or Biological Opinions, the Forest Service, FWS, and NOAA Fisheries must use the best scientific data available. 16 U.S.C. § 1536(a)(2). The agencies must also consider all phases and the entire scope of the agency action. See <i>Conner v. Burford</i>, 836 F. 2d 1521 (9th Cir. 1988); <i>Greenpeace v. NMFS</i>, 80 F. Supp. 2d 1137 (W.D. Wash. 2000). The agencies also cannot arbitrarily limit the time frame of the proposed action. See <i>Wild Fish Conservancy v. Salazar</i>, 628 F.3d 513 (9th Cir. 2010); <i>American Rivers v. U.S. Army Corps of Engineers</i>, 271 F. Supp. 2d 230 (D.D.C. 2003).</p> <p>Additionally, in order to determine whether the proposed project’s adverse impacts may jeopardize one or more of the listed species under the ESA, FWS and NOAA Fisheries must identify each of the species’ tipping points for survival and recovery, and then determine whether the project’s impacts would reach that threshold. <i>Ctr. for Biological Diversity v. Salazar</i>, 804 F. Supp. 2d 987, 999-1000 (D. Ariz. 2011). The agencies must know at what point survival and recovery will be placed at risk for each species before they can conclude whether or not jeopardy may result from further impairments to habitat that is already degraded. <i>Nat’l Wildlife Fed’n v. Nat’l Marine Fisheries Serv.</i>, 524 F.3d 917, 936 (9th Cir. 2008).</p> <p>During the Section 7 consultation, FWS and NOAA Fisheries may rely on mitigation measures “only where they involve ‘specific and binding plans’ and ‘a clear, definite commitment of resources for future improvements’ to implement those measures.” <i>Ctr. for Biological Diversity</i>, 804 F. Supp. 2d at 100, quoting <i>Nat’l Wildlife Fed’n</i>, 524 F.3d at 935-36. Furthermore, “mitigation measures supporting a [biological opinion’s] no jeopardy or no adverse modification conclusion must be ‘reasonably specific, certain to occur, and capable of implementation; they must be subject to deadlines or otherwise-enforceable obligations; and most important, they must address the threats to the species in a way that</p>		

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>satisfies the jeopardy and adverse modification standards.” Id., quoting Ctr. for Biological Diversity v. Rumsfeld, 198 F. Supp. 2d 1139, 1152 (D. Ariz. 2002).</p> <p>Overall, despite the anticipated, significant adverse impacts to listed species and critical habitat, the SDEIS fails to demonstrate that the proposed Project can meet the strict standards under the ESA to protect the listed species and to ensure that there will be no destruction or adverse modification of their designated critical habitats. The commenters request copies of the biological opinions for the proposed Project as soon as they are completed and available.</p>

Benjamin Davenport, Executive Director, Idaho Mining Association	18777	3	<p>III. Recent Administrative and Congressional Critical Minerals Directives</p> <p>The SGP embodies several key objectives in the Administration's and Congress' recent critical minerals policies. First, the SGP will become the Nation's only source of domestically mined antimony⁵, which is one of the critical minerals included in the U.S. Geological Survey's (USGS') critical minerals list⁶. Secondly, as a remining project, the SGP is a perfect demonstration project for the remining goals embraced in recent statutes, Executive Orders, and other federal decisions. The remining components of the SGP include:</p> <ol style="list-style-type: none"> 1) Reprocessing and recovering gold and antimony from legacy mine wastes with recoverable metal values; and 2) Removing non-valuable mine wastes from area streams where they are currently leaching metals and degrading water quality and placing these wastes in modern, engineered facilities designed to isolate these materials from the environment. <p>As explained in the DoD's DPA award announcement, the U.S. military has a critical need for the antimony from the SGP:</p> <p>"This investment is essential to ensure the timely development of a domestic source of antimony trisulfide for the manufacture of small arms and medium caliber cartridges, as well as many other missile and munition items."</p> <p>Since publication of the Draft EIS in August 2020, there have been several Administrative and Congressional critical minerals actions that are directly relevant to the SGP including the following:</p> <ul style="list-style-type: none"> • President Trump's September 30, 2020 Executive Order 13953 entitled "Addressing the Threat to the Domestic Supply Chain from Reliance on Critical Minerals from Foreign Adversaries;" • President Biden's February 24, 2021 Executive Order 14017 "On America's Supply Chains." <ul style="list-style-type: none"> • This Executive Order directed the Secretaries of Commerce, Energy, Defense, and Health and Human Services to complete a supply chain review in 100 days and specified that the Secretary of Defense must prepare "a report identifying risks in the supply chain for critical minerals" and describe and update the work done pursuant to President Trump's Executive Order 13953 on critical minerals. • The June 2021 report "Building Resilient Supply Chains, Revitalizing American Manufacturing, and Fostering Broad-Based Growth," which is the 100-day Supply Chain Review Report prepared in response to Executive Order 14017; 	REG	<p>No further response required. General in nature or position statement.</p> <p>The Forest Service's consideration of the Project on the basis of its ability to produce gold, silver, and antimony is described in SDEIS Section 1.6 as the Project's Purpose and Need.</p>

			<ul style="list-style-type: none"> • The March 2022 “Request for Information (RFI) to inform the Interagency Working Group on Mining regulations, Laws, and Permitting” in the Federal Register (Vol 87, No. 62) published by the Office of the Secretary of the Department Interior. • One of the questions in the IWG’s RFI pertains specifically to critical minerals and asks: “What types of incentives would be appropriate to encourage the development of critical minerals?;” and • The March 2022 announcement that President Biden was invoking his authority under Title III of the Defense Production Act and gave the Department of Defense the authority to increase domestic mining and processing of critical minerals that are used for storage batteries. <p>The June 2021 100-Day supply chain report includes a 53-page critical minerals section prepared by the DoD that outlines the following key findings:</p> <ul style="list-style-type: none"> • Strategic and critical minerals and materials are the building blocks of a thriving economy and a strong national defense. • Critical minerals and materials are used in nearly every electronic device, support high value-added manufacturing and high-wage jobs, in numerous sectors; • The global strategic and critical materials and minerals supply chains are at serious risk of disruption—from natural disasters or <i>force majeure</i> events, and are rife with political intervention and distortionary trade practices. • This risk is more than a military vulnerability; it impacts the entire U.S. economy and our values. • The need for strategic and critical materials is likely to intensify to enhance or enable many environmentally friendly “green” technologies, such as electric vehicles, wind turbines, and advanced batteries. • Expanding U.S. production and processing capacity will require investments in mining, including in non-traditional types of mining, in processing, and in recycling. <p>The 100-day supply chain report is directly relevant to the SGP because this report explicitly requires the Secretaries to evaluate reprocessing mine wastes as a viable source of critical minerals. As a remining and reprocessing project that will recover the critical mineral antimony from legacy mine wastes, the SGP is exactly the type of remining project described in the 100-Day Report.</p>		
Benjamin Davenport, Executive Director, Idaho Mining Association	18777	13	<p>VIII. The Rosemont Case is not Applicable to the SGP</p> <p>Based on two of the alternatives that the Forest Service appropriately eliminated from additional analysis, it appears that project opponents are seeking to apply an Arizona federal District Court’s decision in litigation pertaining to the proposed Rosemont copper mine to the SGP13. Their efforts misapply the <i>Rosemont</i> Court’s ruling, which cannot be extrapolated or applied by analogy to other proposed mining operations due to the different, unique, and site-specific geological and land configuration facts at the Rosemont Project compared to other mineral deposits.</p> <p>Section 1.10.3.1 of the SDEIS discusses why the Forest Service eliminated “Changes to the General Mining Law” as an issue warranting additional analysis. In this section, the Forest Service correctly characterizes the Mining Law as a land tenure statute that governs property rights and explains that it is not an environmental protection statute¹⁴. The Mining Law gives citizens the right to enter, use, and occupy federal lands open to location for mineral exploration and development purposes.</p> <p>Section 1.10.3.2 of the SDEIS explains that the Forest Service eliminated using its special use regulations at 36 CFR 251 Subpart B (the 251 regulations) to evaluate the SGP from additional analysis in the SDEIS because these regulations do not apply to mining. As correctly discussed in Section</p>	REG	No further response required. General in nature or position statement.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>1.10.3.2, Section 251.50(a) explicitly exempts mining from these special use regulations. The Forest Service correctly eliminated both issues from detailed analysis in the SDEIS because</p> <p>The record before the <i>Rosemont</i> Court emphasizes that the lands proposed for mine waste disposal facilities (e.g., waste rock and tailings storage areas) were unmineralized and that mining claims had been located on these lands. In <i>Rosemont</i>, the District Court ruled that these mining claims were invalid. However, this ruling is unique to the on-the-ground facts at the Rosemont Project as dictated by the geology and land configuration at Rosemont. Therefore, the District Court's holding in <i>Rosemont</i> is not a blueprint for any other proposed mining project because the geology and land configurations are different for every mineral deposit. Each mineral deposit's unique geological characteristics means the appropriate arrangement for mining claims and mill sites must be custom-tailored to fit that deposit's geologic facts.</p> <p>As affirmed by the <i>Rosemont</i> court, the Mining Law authorizes locating mining claims on lands that are mineral in character and mill sites on lands that are not mineral in character¹⁵. Mill sites can be used for ancillary mining features such as development rock and tailings storage facilities that are needed to support mining activities. As is readily evident from Figure 3.9-3, "Stibnite Mining District Geology" in the SDEIS, Perpetua is proposing to locate the tailings impoundment and associated embankment/buttress on lands in the Meadow Creek drainage that are not mineralized. Mill sites could be located on these non-mineralized federal lands pursuant to Section 42 of the Mining Law.</p>		
Jolie Drake	18929	2	<p>Unfortunately, the antiquated General Mining Act of 1872 gives Perpetua (or anyone, foreign or domestic) the right to mine on Idaho land while paying zero royalties. However, this act does not also grant them the right to cause environmental damage or harm the recreational use and enjoyment of nearby areas. This SDEIS does not provide the breadth and granularity required to fully assess the risks and required mitigation for a project of this scope. Nor did the abbreviated comment period allow adequate time for a thorough enough review of a project of this magnitude.</p>	REG	<p>SDEIS Chapter 4 analyzed the potential Project effects on 23 classifications of environmental resources present in the Project vicinity. The Final EIS includes expanded discussion of mitigation measures per that analysis and public comments received on the SDEIS.</p> <p>The 75-day public comment period was deemed adequate for public review of the SDEIS.</p>
Jolie Drake	18929	7	<p>With all the environmental risks associated with the Perpetua mining project, and lack of sufficient federal oversight, we should not support nor allow this project to move forward. In spite of the 1872 mining act, there is recent precedent for denying a minerals mining permit. Last year, the federal government blocked the Twin Metals copper mine along the pristine Boundary Waters in northern Minnesota and in late 2020, the Pebble Mine gold mine project was denied by the U.S. Army Corps of Engineers because it could not adequately comply with Clean Water Act guidelines, thus they concluded "the proposed project is contrary to the public interest." I would propose that similar justification is equally warranted in this sensitive and unique habitat in Idaho.</p>	REG	<p>No further response required. General in nature or position statement.</p>
Pam Wissenbach	19213	3	<p>Question two is why doesn't Perpetua have to bond using cash, not company stock? There is no way to know what the stock will be worth in the future or if the company will be in business.</p>	REG	<p>Reclamation performance bonds for plans approved by the Forest Service must comply with FSM 6560 which does not allow a Principal to self-bond with company stock.</p>
Karen Balch (North Fork Veterinary Service)	19228	3	<p>However, in 2012, Midas Gold Corp. proposed exploration for possible future mining of gold, silver, antimony at the Stibnite, Yellow Pine mine site. As one the of the first citizen appellants, I began to feel that the USFS appeared to be "advocates" in promoting the mining company rather than representing the American public who own the federal lands. I was perplexed why it seemed that the USFS seemed to be acting on behalf of the mining companies. But it's a perception that has persisted throughout this whole process to me. Sadly, I have felt throughout this ongoing process review that the USFS is more of an adversary rather than a non-biased referee. Maybe that's because I oppose this project on every level and perceive that "by the powers that be" this project is a slam dunk given just moving through the required steps.</p>	REG	<p>Processing of mining permit applications on National Forest System lands is a duty assigned to the Forest Service. The Forest Service does not advocate on behalf of the mine proponent but processes the permit per Forest Service requirements and guidelines.</p>
Alan Haslam (Vice President, Permitting, Perpetua	19325	51	<p>"However, the agency will need to evaluate the eventual applications for rights of way to make a final determination." Recommend removing this passage as inapplicable to a Purpose and Need statement. It should be deleted in the Final EIS. Likely only the IPCo powerline additions and upgrades off-site on NFS lands will be the subject of rights of way applications or amendments under 36 CFR 251 as a third party connected action. As recognized elsewhere in this SDEIS, the remainder of the SGP included in the</p>	REG	<p>Edit has not been made. The statement reflects the agency's duty and the current status of right of way applications.</p>

Resources Idaho, Inc.)			2021 MMP, including access roads on NFS lands, will properly be the subject of review and approval of the plan of operations under 36 CFR 228A.		
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	52	<i>"All functions, work, and activities on NFS lands in connection with prospecting, exploration, development, mining, or processing of mineral resources and all uses reasonably incident thereto, including roads that are constructed and maintained in connection with development and mining of mineral resources, are operations authorized by the U.S. mining laws (36 CFR 228.3(a))"</i> - Here and wherever else this sentence may appear in the SDEIS, consider revising "authorized by the U.S. mining laws" to "within the scope of 36 CFR 228 subpart A" to more closely track the text of 36 CFR 228.3(a).	REG	The language of this sentence combines wording from 36 CFR 228.1 and 228.3. The subject wording of this comment, "authorized by the U.S. mining laws" is taken directly from 36 CFR 228.1. The requested edit will not be made in the EIS.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	53	Consider adding reference to the 2016 amendment of the 2012 Planning Rule here, which clarified/refined direction for Forest Plan Amendments.	REG	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	54	Consider adding "as amended" after the reference to 36 CFR 219.13 here.	REG	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	58	<i>"This is dismissed from consideration because making or amending law is an explicit function of Congress and not within the authority of the Secretary of Agriculture, or the Forest Supervisors."</i> Recommend adding: "Also, it is addressed by other laws, regulations, or policies."	REG	The subject paragraph only discusses the 1872 Mining Law itself and not other laws, regulations, or policies. The requested edit will not be made in the EIS.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	59	"36 CFR Part 251 Land Uses" - Recommend that the transmission lines be specifically addressed in this response, to clarify why 251 does not apply to that part of it. Special Use Authorization are mentioned in Table 1.7-2. This is made more of a focus because the transmission line would require forest plan amendments.	REG	The subject paragraph only discusses the response to the prior DEIS comment why the Proposed Action is not being permitted under 36 CFR 251. It does not apply to the third-party power line work. The requested edit will not be made in the EIS.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	75	The presentation of Tables 2.4-12 and 2.4-13 (and similar smaller tables in resource sections of Chapter 4 or Specialist Reports) is somewhat confusing: Table 2.4-12 includes Forest Plan guidelines, design features with regulatory basis, and design features with no regulatory basis listed. It is unclear who developed the stated Design Features, even if a regulation is listed. Table 2.4-13 includes additional proponent proposed design features intended to reduce or avoid environmental impacts that do not include any citations of regulatory basis. We believe the intention of these tables is to separate the features that are required by USFS or another agency (Table 2.4-12) from those that Perpetua has proposed without a regulatory impetus (Table 2.4-13). This is a good goal, and could be better achieved if the first table had a very clear regulatory basis for each entry, and if both tables included citation document for the description of the features (i.e. Forest Plan, Perpetua MMP documents, etc).	REG	Table 2.4-12 in the SDEIS already includes references to the applicable regulatory requirements. This is necessary because these requirements are found in a number of generally applicable documents applicable to any project like the Proposed Action. Adding citations for the project-specific Perpetua 2021 MMP design features in Table 2.4-13 is not necessary because these are described in other parts of the EIS document itself. The requested edit will not be made in the EIS.
Meg FitzMaurice	19329	4	Perpetua Resource Co. has long advertised their intent to "restore" the old Stibnite mining site as part of their efforts. Perpetua advertises on their website "our project is designed to restore the environment." It should be noted that while SMP will in part be located at the old Stibnite mining site over half of the SMP will take place on previously undisturbed lands, the majority of which	REG	No further response required. General in nature or position statement.

			<p>are public lands administered by the National Forest. If Perpetua's intent with SGM is truly to restore the area then:</p> <p>1) Why does it violate the Payette and Boise Land Resource Management Plans? Why does the USFS need to significantly amend the Forest Plan to allow for long term and indefinite degradation of resources, aquatic and wildlife?</p> <p>2) Why does it violate the Clean Water Act?</p> <p>3) Why does it violate the Endangered Species Act?</p> <p>4) Why does it conflict with established Treaty and Tribal Rights?</p> <p>5) Why does the SDEIS lack detailed reclamations plans or analysis of the effectiveness of the limited proposed mitigation measures?</p>		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	143	<p>2. Clean Water Act Regulatory Evaluation</p> <p>The proposed mine would fill and disturb wetlands and streams, all Waters of the United States, including many wetlands. Currently, the Army Corps and U.S. EPA interpret Waters of the United States as consistent with the pre-2015 regulatory regime until further notice. Under Section 404 of the federal Clean Water Act (CWA), there are two types of authorizations — general permits, and standard or individual permits. In the case of this proposed mine, an individual permit would be the applicable type of authorization. An individual permit can be issued only if the proposed discharge complies with the environmental standards under Section 404(b)(1), also known as the 404(b)(1) Guidelines (the Guidelines), which are binding regulations. The Guidelines set out four independent tests for permit issuance, described below.</p> <p>a. Section 230.10(a): Except as provided under section 404(b)(2), no discharge of dredged or fill material shall be permitted if there is a practicable alternative to the proposed discharge which would have less adverse impact on the aquatic ecosystem, so long as the alternative does not have other significant adverse environmental consequences. (This standard is referred to as the LEDPA, or least environmentally damaging practicable alternative.)</p> <p>b. Section 230.10(b): No discharge of dredged or fill material shall be permitted if it [among other things], (1) Causes or contributes, after consideration of disposal site dilution and dispersion, to violations of any applicable State [or approved Tribal] water quality standard; ...</p> <p>c. Section 230.10(c): Except as provided under section 404(b)(2), no discharge of dredged or fill material shall be permitted which will cause or contribute to significant degradation of the waters of the United States. ...</p> <p>d. Section 230.10(d): Except as provided under section 404(b)(2), no discharge of dredged or fill material shall be permitted unless appropriate and practicable steps have been taken which will minimize potential adverse impacts of the discharge on the aquatic ecosystem.</p> <p>If a proposed discharge is found to comply with the Guidelines, the Army Corps then must make a determination of whether the proposed project would be contrary to the public interest.</p>	REG	No further response required. General in nature or position statement.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	144	<p>3. Section 230.10(a): Alternatives</p> <p>An alternatives analysis under NEPA is separate and distinct from what is required under the 404(b)(1) Guidelines. The standards are not identical: for example, NEPA is non-regulatory and requires disclosure and evaluation of a reasonable range of alternatives; Section 404 is regulatory and the Guidelines allow only the least environmentally damaging practicable alternative (LEDPA) to be authorized under the CWA. While this might lead to some differences in the NEPA and 404 analyses, the Corps and federal and state resource agencies typically work to integrate the information requirements under both processes to the extent appropriate and feasible.</p> <p>Key to evaluating alternatives under CWA Section 404 is determining the Basic Project Purpose and the Overall Project Purpose of the proposed mine. In this case, the Forest Service determined that the Basic Project Purpose is to extract gold, silver, and antimony from ore. The SDEIS states that the Overall</p>	REG	The location of the mining operations described in the Proposed Action is fixed by the occurrence of the mineral resources in that location that are controlled by the proponent. There are no reasonable alternatives to that general location. The rest of this comment is general in nature and no further response is required here.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>Project Purpose is to mine, gold, silver, and antimony from ore deposits associated with SGP’s mining claims and rights in Valley County, Idaho.” (emphasis added). Though the first part of the Project Purpose is fine, the emphasized portion is where the Service erred. Fastening the analysis of alternatives to the SGP in a specific location automatically constrains that analysis to that location and renders the alternatives analysis meaningless.</p> <p>An overall project purpose will normally describe the proposed activity in order to characterize the applicant’s fundamental objectives. Practicable alternatives (see discussion below) are examined in light of overall project purposes. An overall project purpose defined too generally could theoretically require examination of countless potential alternatives; conversely an overall project purpose framed too specifically could automatically eliminate everything but the applicant’s proposed alternative from consideration; this appears to be the case here. In most cases, the project purpose is framed so that it is neither so broad (e.g., “to operate a profitable business”) as to involve consideration of an unwieldy number of alternatives nor so narrow as to constrain the analysis unreasonably, as was done by the Forest Service for this proposed mine project.</p> <p>While determining the overall project purpose is necessarily somewhat case-specific, the intent is to capture the fundamental objectives of a project (i.e., mining for the ore bodies described). Doing so enables an evaluation of potentially practicable and less environmentally damaging alternatives during the permit review process while also bounding the analysis to avoid spending time on alternatives that simply could not meet the project’s purpose. Potentially practicable and less environmentally damaging alternatives include existing or previously closed mining operations or alternative ore deposits that are or were available to the applicant when it entered the market. By improperly defining the overall project purpose too narrowly, the Service’s analysis fails to assess the possibility that less environmentally damaging practicable alternatives may, in fact, exist.</p> <p>Applicants, particularly those well along in project planning or who already invested time and resources in a particular proposal (as is the case here), may naturally desire an overall project purpose statement that contains a number of specifics aimed at increasing the likelihood that the alternatives analysis will lead to the project they already have in mind. However, the regulations require a credible alternatives analysis be performed, one that aims to identify the LEDPA rather than a proposed project “justification” analysis that steers toward a predetermined outcome.</p> <p>Finally, the 404(b)(1) regulations place the burden of proof squarely on the applicant to prove that its proposal is the least damaging alternative if the applicant’s project would discharge dredged or fill material in “special aquatic sites” for purposes that are not water-dependent. The level of documentation should reflect the significance and complexity of the discharge activity.¹⁷⁶ Therefore, the applicant is required under the regulations to “clearly demonstrate” that less environmentally damaging alternatives do not exist. In the absence of such a clear showing, the Corps is required to deny the application for a permit.</p> <p>Section 230.10(a) of the Guidelines requires that;</p> <p>(a) Except as provided under section 404(b)(2), no discharge of dredged or fill material shall be permitted if there is a practicable alternative to the proposed discharge which would have less adverse impact on the aquatic ecosystem, so long as the alternative does not have other significant adverse environmental consequences.</p> <p>(1) For the purpose of this requirement, practicable alternatives include, but are not limited to:</p> <p>(i) Activities which do not involve a discharge of dredged or fill material into the waters of the United States or ocean waters;</p> <p>(ii) Discharges of dredged or fill material at other locations in waters of the United States or ocean waters;</p> <p>(2) An alternative is practicable if it is available and capable of being done after taking into consideration cost, existing technology, and logistics in light of overall project purposes. If it is otherwise a practicable alternative, an area not presently owned by the applicant which could reasonably be obtained, utilized, expanded or managed</p>		

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>in order to fulfill the basic purpose of the proposed activity may be considered. Neither the SDEIS, the Clean Water Act Section 404 (b) (1) Evaluation Framework for the Stibnite Gold Project (Appendix B to the DEIS),178 nor any of the related documents discuss a thorough evaluation of alternatives, especially other locations for the mine project.</p> <p>Despite how Perpetua presents the proposed project in the SDEIS, it has proposed only one mine site location, with two potential access routes (Johnson Creek Route and Burntlog Route). Though the SDEIS describes a few variations regarding where to locate some facilities for the SGP, e.g., the TSF, most of the variations are simply approaches to minimize adverse impacts to aquatic resources¹⁷⁹ and not substantive alternatives for the mine project. The approaches to minimize impacts are welcome, but those approaches are required for any alternative under both NEPA and CWA Section 404. Perpetua has not identified any alternative sites for the proposed mine itself. Under NEPA, and especially under CWA Section 404, that does not constitute “a range of reasonable alternatives.”</p> <p>As described in the SDEIS, as part of the NEPA process, the USFS conducted an extensive alternatives development, screening, and evaluation process with the participation of the USACE. In the documents reviewed, there is little evidence that the USFS or the USACE “conducted an extensive alternatives development, screening, and evaluation process.” Missing from the alternatives discussion in the SDEIS and its related documents is a discussion of:</p> <ul style="list-style-type: none"> • other sites for the mine and its attendant facilities that were evaluated (not access route variations); • their location, owners, availability; • the aquatic resources present at those other sites; • the anticipated adverse impacts to those aquatic resources that would occur at those sites were a mine to be developed; • conceptually how those adverse impacts could be compensated; and, • for other sites that were evaluated and rejected, the reasons for rejection. 		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	193	<p>6. New road construction for the Burntlog Route violates Forest Service regulations regarding Forest Planning, access across National Forest lands, the Idaho Roadless Rule and Travel Management</p> <p>New construction for the Burntlog Route would violate the Forest Plan. The newly constructed road would pass through Management Areas 20 and 21 which the Forest Service has prioritized for active and passive restoration and maintenance of aquatic, terrestrial, & hydrologic resources. Management actions may only degrade resource conditions for 15 years or less and must be designed to avoid degradation of existing conditions in the long-term: General Standard 2005 Management actions, including salvage harvest, may only degrade aquatic, terrestrial, and watershed resource conditions in the temporary time period (up to 3 years), and must be designed to avoid resource degradation in the short term (3-15 years) and long term (greater than 15 years).</p> <p>General Standard 2010 Management actions, including salvage harvest, may only degrade aquatic, terrestrial, and watershed resource conditions in the temporary (up to 3 years) or short-term (3-15 years) time periods, and must be designed to avoid degradation of existing conditions in the long-term (greater than 15 years). The Burntlog Route construction, operations and obliteration will result in over 20 years of negative impacts to aquatic, terrestrial, & hydrologic resources, in direct violation of the Forest Plan. Road construction is deemed so incompatible with protecting these resources that the Standards 2008, 2012 and 2015 have a prohibition on road construction not related to the identified exemptions: Road construction and reconstruction may only occur where needed: a) To provide access related to reserved or outstanding rights, or b) To respond to statute or treaty, or c) To address immediate response situations where, if the action is not taken, unacceptable impacts to hydrologic, aquatic, riparian or terrestrial resources, or health and safety, would result. And Standards 2050 and 2154: New roads shall not be built except to replace existing roads in RCAs or directly repair human-caused damage to TEPC fish habitat in streams unless it can be demonstrated through the project-level NEPA analysis and related Biological Assessment that adverse effects to TEPC species or their habitats are avoided unless outweighed by demonstrable short- or long-term benefits to those TEPC species or their habitats. New road construction for the Burntlog Route will also violate several Forest Plan objectives (Boise Forest</p>	REG	The reroute of Stibnite Road and the designation of a temporary OSV route to replace an existing OSV route are actions that fall under the Travel Management Rule (36 CFR 212), Subparts B and C respectively (FSM7715.03(5)). These actions require consideration under the Travel Management Rule Minimization Criteria (36 CFR 212.55(b)). The Travel Management Rule analysis was added to Section 4.19 of the Final EIS.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>Plan III-376): Objective 2014 Improve water quality by reducing road-related accelerated sediment delivery to upper Johnson Creek and its tributaries.</p> <p>Objective 2015 Assist in de-listing South Fork of Salmon River drainage, including upper Johnson Creek, from the State of Idaho's impaired water bodies list by applying appropriate and active watershed restoration to reduce sediment, which is the identified pollutant of concern.</p> <p>Objective 2016 Improve stream bank stability by reducing sediment delivery to Johnson Creek, and by revegetating banks with native plant species as needed.</p> <p>Perpetua is proposing construction and operations related to the Burntlog Route to provide access related to reserved or outstanding rights. However, as detailed above, there is already reasonable access to the Stibnite area by way of Forest Roads 412 and 375 as evident with the Forest Service's development of the Johnson Creek Alternative. These same roads previously supported decades of large scale mining activities, including open pit cyanide leach operations. There are also doubts about whether all of Perpetua's claims are valid, as detailed above. As such, we do not believe that any Forest Plan amendments to allow additional road construction are needed or legally supportable.</p> <p>New construction for the Burntlog Route also violates National Forest travel regulations. Forest Service regulations provide that "Where there is existing access [...] that is adequate or that can be made adequate, there is no obligation to grant additional access through National Forest System lands." (36 C.F.R. 251.110(c) and (g)).</p> <p>The Burntlog Route is also impermissible under the Idaho Roadless Rule (36 C.F.R. 294, Subpart C). The Idaho Roadless Rule generally prohibits road construction in Idaho Roadless Areas (IRA), including the Black Lake (5,335 ac.) and Burnt Log (23,699 ac.) roadless areas through which the proposed Burntlog Route would pass. The large majority of land in these two IRAs is classified by a "Backcountry/ Restoration" management theme by the Idaho Roadless Rule. DEIS at 3.23-7. The Rule provides a limited exception for road construction to access valid existing claims when it is found to be needed: "Road construction is only permissible in Idaho Roadless Areas designated as Backcountry/Restoration when the Regional Forester determines ... (iii) A road is needed pursuant to statute, treaty, reserved or outstanding rights, or other duty of the United States." 36 CFR § 294.22(b)(1) (emphasis added). The inclusion of the word "needed" is significant in the consideration of the road construction associated with this project. It requires the Regional Forester to consider the necessity of the road construction in balancing the underlying intent and direction of the roadless rule (to protect roadless values and integrity) with any statutory and/or outstanding rights. In this instance there is no "outstanding right" because that right is currently satisfied by existing access along the Johnson Creek and up the East Fork South Fork Salmon River (identified as the Yellow Pine Alternative in the DEIS and the Johnson Creek Alternative in the SDEIS) which does not bisect roadless areas.</p> <p>The limitation on the construction and use of temporary roads for administrative purposes is reiterated in the FEIS for the Idaho Roadless Rule, which states "Temporary roads are not intended for public use and are not subject to the Highway Safety Act of 1966." Public motorized use of the road would not be an administrative use, and therefore the proposal to authorize it is inconsistent with the Idaho Roadless Rule.</p> <p>Allowing public motorized use on the new 15 miles of the Burntlog Route would violate the Travel Management Rule which limits motorized public access to roads, trails and areas designated for motor vehicle or over-snow vehicle use (36 C.F.R. 261.13). The Forest Service is classifying the 20-year+ Burntlog Route as a temporary road needed to provide access to mineral claims under the Mining Law of 1872. The Idaho Roadless Rule specifically incorporates definitions of Forest Roads and Temporary Roads from 36 CFR § 212.1. According to those definitions, a temporary road is "authorized by contract, permit, lease, or other written authorization that is not a forest road or trail and that is not included in a forest transportation atlas." The Idaho Roadless Rule goes on to clarify (36 CFR Part, Subpart C, § 294.21 Definitions) that "Temporary roads are available for administrative use until decommissioned."</p>

			<p>Setting aside the issue that the Burntlog Route is not consistent with the Idaho Roadless Rule and Payette Forest Plan, the Burntlog Route should not be available for public motorized use as a Forest Road or Trail (some motorized trails overlap with Forest Service administrative roads on the Payette). The proposed new section of the Burntlog Route is not included in the Forest Transportation Atlas, is not considered a Forest Road, has not been designated for motor vehicle or OSV use (36 C.F.R. 261.13) and is therefore only available for administrative use and implementation of the Special Use Permit, and not public motorized travel.</p> <p>However, the Forest Service is considering allowing public motorized use of the Burntlog Route during the approximate one year time in which the replacement Stibnite Gold public access road is being constructed from the north part of the Operations Area, through the mine site, and on to Thunder Mountain: The newly constructed Burntlog Route connecting to Thunder Mountain Road would be a temporary road necessary for mining purposes and would meet 36 CFR 228A requirements for environmental protection to assume that mine operations are conducted to minimize adverse environmental impacts to the extent feasible for roads. Accordingly, the road would not be designated for public motor vehicle use under 36 CFR 212.50 on the Motor Vehicle Use Map. Therefore, for public motor vehicle use to be allowed on the road when other public access roads are blocked by mine operations, one of the other exceptions from the prohibitions on motor vehicle use on NFS land at 36 CFR 261.13 must be met. The approved plan of operations would meet the exception for written Forest Service authorization under 36 CFR 261.13(h) by including a provision in the mine plan for public use of the road when other public road access is blocked by mine operations. SDEIS 4-490.</p> <p>The Forest Service is considering utilizing 36 CFR 261.13(h) which allows the Forest Service to authorize motor vehicle use under a written authorization:</p> <p>(h) Motor vehicle use that is specifically authorized under a written authorization issued under Federal law or regulations; However, this exemption was never intended to be used so broadly. The Forest Service travel management directives state, "Examples of a written authorization include contracts, easements, and permits." (FSM 7716.2(1)(h)). Contracts, easements, and permits are not issued to the general public. They are issued to entities that have approved for special uses. Therefore, it is illegal to authorize public use of the Burntlog Route under this exemption. Even if the Forest Service were to authorize construction and public use of the Burntlog Route, the agency would have to properly adhere to Subparts B and C of its travel management regulations.</p> <p>Such a federal action would still have to be consistent with NEPA and the NEPA analysis for such a proposal here is clearly lacking. Furthermore, 36 CFR 261.13(h) was never intended to open such a sensitive route for public access for that duration.</p> <p>By setting this precedent, the Forest Service will open itself up to an expectation that the Forest Service will open the Burntlog Route whenever the Johnson Creek Route/Stibnite Road is closed for any length of time. The replacement public route through the Operation Area to Thunder Mountain will not be open for at least a year while it is being constructed and will also be closed for several days each year due to any number of reasons: mining sequencing such as blasting and hauling, avalanches along the Stibnite road, spill cleanups, or other issues. The Specialist Report appears to confirm this expectation: Burntlog Route, which would be open to public use when other routes into the area are not available, could increase disturbance to wildlife species as the public could use the road at any time of day.²³⁹ (Emphasis added.)</p> <p>Using 36 CFR 261.13(h) in this circumstance sets a bad precedent for other issues where the Forest Service has determined that increased motorized recreational activity will have negative environmental impacts.</p> <p>Regardless of whether or not general or specific criteria apply, the agency must demonstrate how its "written authorization" complies with the Travel Management Rule, including how the environmental analysis in support of that authorization demonstrated the agency adequately considered the general effects, and the minimization criteria (if applicable). The Forest Service would need to demonstrate how it considered public motorized use of a new road within an IRA in its written authorization and would</p>		

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>require supporting analysis that addresses impacts to roadless characteristics (i.e., natural resources), quiet recreational opportunities, and conflicts among uses of NFS lands, especially if those lands have a semi-primitive, non-motorized setting. Specifically, 36 CFR 212.55(a) states in part: "the responsible official shall consider effects on National Forest System natural and cultural resources, public safety, provision of recreational opportunities, access needs, conflicts among uses of National Forest System lands, the need for maintenance and administration of roads, trails, and areas that would arise if the uses under consideration are designated; and the availability of resources for that maintenance and administration." We maintain that the road should not be open to public motorized use absent a travel management designation decision consistent with subpart B of the Travel Management Rule (and consistent with the Roadless Rule as well, given location through an IRA).</p>		
<p>Bonnie Gestring (Northwest Program Director, Earthworks) and seven others</p>	<p>17634</p>	<p>213</p>	<p>An important element of all Forest Service travel management planning is compliance with the "minimization criteria". These criteria were outlined in Executive Orders 11644 and 11989, issued by Presidents Nixon and Carter in 1972 and 1977, respectively. The criteria require federal land management agencies, when designating routes (and areas) open to motorized travel, to: 1) minimize damage to soil, watershed, vegetation, or other resources of the public lands; 2) minimize harassment of wildlife or significant disruption of wildlife habitats; 3) minimize conflicts between off-road vehicle use and other existing or proposed recreational uses of the same or neighboring public lands; and 4) minimize conflicts among different classes of motor vehicle uses of National Forest System lands or neighboring Federal lands.²⁴² The Forest Service codified these "minimization criteria" in subparts B and C (the OSV Rule) of its travel management regulations.²⁴³ When modifying the snowmobile trail system, designating new OHV routes, or making other determinations that affect motorized use of routes or areas the Forest Service is required to abide by the minimization criteria.</p> <p>REST04 in the Payette Forest Plan states that "On all lands outside of designated travel ways, motorized use shall be prohibited unless otherwise authorized." Neither of the two proposed new OSV routes in the SDEIS alternatives are currently designated OSV routes on the Payette National Forest.</p> <p>In order to designate these routes – even as temporary routes – the Forest Service must follow the requirements of the Travel Management Rule and comply with the minimization criteria. The fact that the area through which the proposed OSV routes would travel is not closed to OSV use does not affect the need to adhere to Travel Management regulations when designating these routes as groomed OSV routes. The Payette National Forest has not conducted Subpart C travel management planning, and thus has not gone through a process to determine where OSV use is appropriate. The forest is continuing to operate under a pre-Travel Management Rule paradigm of "open unless designated closed", which is incompatible with current agency policy. Committing to a 20-year groomed OSV trail in the absence of any travel management decisions contravenes agency policies and prejudices the future Subpart C process. Elsewhere in the Forest Service system the agency has acknowledged that grooming increases OSV use by over 50%²⁴⁴ — thus, designating new groomed routes is likely to have significant impacts on wildlife, natural resources, and other uses.</p> <p>In response to litigation from Winter Wildlands Alliance, The Wilderness Society, and WildEarth Guardians, the Payette National Forest clarified that it administers over-snow motor vehicle use in accordance with prior decisions and that the Forest Service needs to conduct winter travel planning.²⁴⁵ Section 3.16.2.3 is the only part of the DEIS that addresses the Travel Management Rule. Although this section briefly describes the Rule, and states in that "The Forest Service issued orders including maps showing the areas where OSV use is allowed, prohibited, or restricted", this statement should be amended to clarify that these orders — and the forest — are not compliant with Subpart C of the Travel Management Rule. This section of the SDEIS should also state that any new ORV — including OSV — designations necessitate application of the Travel Management Rule. Specifically, if the Payette Forest wishes to designate new ORV routes (and parking areas) to offset routes lost to the Stibnite Gold Project, it must ensure that the new routes are located in a manner that minimizes damage to natural resources, minimizes harassment of wildlife or significant disruption of wildlife habitat, minimizes conflict between uses, and minimizes conflict between differing classes of motor vehicles. Of particular concern</p>	<p>REG</p>	<p>The reroute of Stibnite Road and the designation of a temporary OSV route to replace an existing OSV route are actions that fall under the Travel Management Rule (36 CFR 212), Subparts B and C respectively (FSM7715.03(5)). These actions require consideration under the Travel Management Rule Minimization Criteria (36 CFR 212.55(b)). The Travel Management Rule analysis was added to Section 4.19 of the Final EIS.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>for our organizations, given the location of these proposed routes, is the impact that each route will have on wildlife populations and on roadless characteristics.</p> <p>The SDEIS does not even mention that there are requirements the Forest Service must abide by when designating ORV routes, including groomed snowmobile trails, much less apply these requirements to the proposed new routes. The Forest Service must explain how taking actions that could dramatically increase OSV use on the Cabin Creek Road and along Johnson Creek will satisfy the requirement to minimize harassment of wildlife or significant disruption of their habitat. If these routes cannot be located in a manner that complies with the minimization criteria, they cannot be designated.</p> <p>The Forest Service's assertion that these trails can be authorized under 36 CFR 228A as part of a plan of operations²⁴⁶ is incorrect. Access and infrastructure for recreation is not necessary to conducting mine operations. Designating routes for recreational use and access falls squarely under the Travel Management Rule. While the Forest Service can certainly designate routes for this purpose as part of the Stibnite Gold Mine NEPA analysis, it must apply the requirements of the Travel Management Rule when doing so.</p>		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	221	The SDEIS fails to discuss in any way what impact the proposed OSV route along Johnson Creek will have. Because the Payette National Forest has not conducted winter travel management planning in accordance with Subpart C of the Travel Management Rule, it cannot assume that its existing system of OSV routes and areas comply with this Rule. The forest must apply the OSV Rule when designating new OSV routes in association with this project, even if the new routes are temporary or are adjacent to an existing route. Therefore, even though the Johnson Creek route will parallel an existing OSV route (the Johnson Creek road), the Forest Service cannot assume that a) the impacts of this route are the same as the existing route or b) that the existing route complies with the Travel Management Rule.	REG	The reroute of Stibnite Road and the designation of a temporary OSV route to replace an existing OSV route are actions that fall under the Travel Management Rule (36 CFR 212), Subparts B and C respectively (FSM7715.03(5)). These actions require consideration under the Travel Management Rule Minimization Criteria (36 CFR 212.55(b)). The Travel Management Rule analysis was added to Section 4.19 of the Final EIS.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	225	As recounted elsewhere, this violates the Idaho Roadless Rule and the Forest Plan. The added recreational pressures on this area are in no way related to mining activities and would make the mining impacts on ecological integrity even worse instead of mitigating them. As such, the Forest Service should make as few changes in existing recreational access as possible and not expand motorized use unless necessary. The Forest Service and Perpetua should continue to allow public access through the Stibnite Operational Area on to Thunder Mountain, with a new route sited through the project area to avoid mining operations. As noted elsewhere, we believe that this is a public road and that Perpetua and the Forest Service need to utilize the normal ambient air quality standards for members of the public on this route. To manage public expectations and avoid delays, we recommend that Perpetua and the Forest Service have a web page describing the estimated schedule and potential closure times for each day and week.	REG	<p>The proposed public access road through the operations area would avoid interaction with mining activities. The EPA and IDEQ agree that the public access road through the proposed mining operations area would be under the control of Perpetua while mining is in progress. They have concluded that ambient air quality standards would not apply to the road during this time.</p> <p>The recommendation for up-to-date scheduling of when public access might be interrupted on certain roads has been included in the EIS as a mitigation measure.</p>
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	379	<p>CC. Additional Review of State Regulations Needed</p> <p>In the SDEIS, the Forest Service consistently defers to the state of Idaho on issues involving the management of federal lands and the effects on public resources. In many instances, the Forest Service assumes to some degree that various state processes have sufficiently addressed key resource issues associated with the SGP. However, these state rulemaking and permitting processes may actually have fewer safeguards in place to protect taxpayers, public health, water quality, fisheries and wildlife compared to NEPA and other federal laws.</p> <p>Perpetua Resources has been closely involved in several recent state rulemaking and permitting processes that will impact the SGP. These include the Idaho Department of Lands rulemaking regarding financial assurances and cyanidation regulations, and Idaho Department of Environmental Quality's air quality permit. In each of these instances, the mining company successfully reduced the permitting requirements or safeguards for key elements over the objections of conservation organizations and others. Groups like the Idaho Conservation League had pointed out that the new proposed rules and permits are less protective than regulations in other states. The federal government was not directly involved in the rulemaking processes or air quality permitting, but the EPA did comment on the final draft of the state air permit expressing significant concerns.</p>	REG	This comment suggests that the Forest Service is deferring to state regulatory programs for the environmental analysis. This is not correct. The SDEIS clearly identifies the state regulatory programs that would apply to the Proposed Action and where the state has created certain environmental standards that would apply to the project these have been included in the EIS. The Forest Service has not deferred the necessary hard look at the environmental impacts required under NEPA and has required Perpetua to provide separate environmental documentation to support the NEPA analysis separately from what they may prepare for the state agencies. An example of this is discussed in Section 4.3 of the SDEIS where separate air emission inventory and air quality impact modeling was required by the Forest Service to support its evaluation of the reasonably foreseeable impacts as required under NEPA. The Forest Service NEPA air impact evaluation included impacts from fugitive dust emission as well as off-site vehicle emissions.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>State regulatory and land management agencies have professional staff who are dedicated to their jobs. However, the state of Idaho and state agencies are not subject to many of the same standards, requirements, safeguards and the multiple-use mission that the federal government must meet. The state of Idaho also prides itself on being the “least regulated state in the Union” and has a gubernatorial directive to remove two regulations for every one passed. This is why it is critically important that the Forest Service carefully scrutinize the permits issued by the State of Idaho regarding the SGP; and, if the state permit conditions do not meet the federal standards for the protection of public resources and multiple uses, the Forest Service must apply more protective measures and/or permit conditions as required by federal policy, rules and law.</p>		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	380	<p>1. Financial assurances</p> <p>Perpetua’s staff and attorneys participated in state rulemaking regarding financial assurances for mining operations. Perpetua convinced the Idaho Department of Lands to accept corporate guarantees as a financial assurance in replacement of cash as a bonding mechanism. Corporate guarantees are essentially a promise to pay based on the reputation and brand of the mining company. Corporate guarantees have proven to be problematic based on numerous examples of mining companies being unable to pay for long term water treatment costs. In fact, Idaho taxpayers are still covering the long term water treatment costs of Asarco’s Triumph Mine. The Forest Service did not participate in this rulemaking.</p> <p>While the majority of the Stibnite Gold Project is on federal land, some portions are on private property owned by Perpetua. It is unclear if the new state bonding regulations - which can be much cheaper for the mining company and far less protective to taxpayers - would apply to the private properties within the Operations Area Boundary or if the federal bonding requirements would apply to the entire project.</p> <p>We are concerned that if the less protective state bonding rules are utilized for the sections of private property, the financial assurances will ultimately be insufficient to pay for successful reclamation on that property. With insufficient reclamation on private properties, we are concerned that environmental problems originating on private property can affect nearby public resources on National Forest System lands. Potential issues include slope instability, increased sedimentation, noxious weeds, heavy metal seepages and water temperatures too high for one or more listed fish species.</p> <p>As such, we strongly recommend that the federal bonding mechanism be used across the entire project area, including across private properties, and that Corporate Guarantees do not play any role in the financial assurance mechanism. We also recommend that the Forest Service include both the reclamation plan and the bonding calculations in a Supplemental SDEIS so the public can have a say in these critical negotiations. Please see our other comments on bonding for additional details.</p>	REG	<p>Reclamation performance bonds for mine plans approved by the Forest Service must comply with FSM 6560 which does not allow a Principal to self-bond with company stock. The acceptable types of surety include surety bond, cash in lieu of bond, letter of credit, or long-term trust.</p>
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	381	<p>2. Cyanidation</p> <p>The staff and attorneys of Perpetua’s predecessor, Midas Gold, participated in a state rulemaking regarding cyanidation regulations for mining operations. Midas Gold convinced the Idaho Department of Lands to lower the standards for mine tailings facilities by allowing a single layer liner instead of the previously required double layer. The Idaho Conservation League pointed out that this is inconsistent with requirements in other states and that all liners leak to some extent. The Forest Service did not participate in this rulemaking.</p> <p>We are concerned that the Forest Service is accepting this controversial lower standard as sufficient for the liner of the tailings storage facility. The tailings storage facility needs to contain over 100 million tons of tailings containing toxic materials, prevent infiltration of meteoric water during reclamation and after closure, prevent leakages through the bottom liner, and endure for millenia. If leaks do occur, as our comments point out they are likely to, the long term costs to taxpayers and impacts to downstream resources, including listed fish species, are likely to be extensive and permanent. Instead of deferring to the state on this issue, the Forest Service needs to conduct its own independent review and ensure that public resources are protected.</p>	REG	<p>The proposed tailings storage facility liner system is described in the TSF Liner System subsection of Section 2.4.5.8 of the SDEIS. The liner system consists of two geosynthetic liners the top one being 60-mil LDPE in direct contact with a geosynthetic clay liner (GCL). This liner system would be place over a prepared subgrade of a minimum of 12 inches of earth bedding material. A system of drainpipes would be installed above the liner system to help reduce future hydraulic head on the liner system itself. This is intended to reduce potential leakage through any defects or perforations of the LDPE membrane. If any leakage were to occur, the GCL directly underlying the LDPE membrane is intended to attenuate the leakage. This type of liner system is comparable, or more protective than required by the state regulations for TSF liners in western states with significant mining operations, namely Nevada. When the SDEIS was prepared, it was independent of the state's review of any information submitted by the proponent for their cyanidation permit. Thus, the Forest Service conducted its own impact analysis of the TSF and this is what is included in the SDEIS.</p>

Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	382	<p>3. Air Quality/Permit to Construct</p> <p>When Perpetua Resources (then Midas Gold) submitted its original Plan of Operations, the Forest Service deemed it acceptable to initiate the NEPA process and developed it as Alternative 1 in the DEIS. When the company submitted a Modified Plan of Operations, the Forest Service developed that as Alternative 2 in the DEIS. Now the Forest Service is analyzing another iteration, the 2021 Modified Mine Plan.</p> <p>In each of these cases, the Forest Service deferred to the Idaho Department of Environmental Quality (IDEQ) regarding the Air Quality Permit/Permit to Construct. The Forest Service simply accepted that the initial draft permit was sufficiently protective of public health, water quality, plants and wildlife. However, that initial draft permit overlooked over 90% of arsenic emissions from the fugitive dust that would be generated by mining activities. These high levels of arsenic would have had significant impacts on the public and the public resources the Forest Service manages. The Idaho Conservation League and other organizations successfully objected to this permit. A subsequent version of the draft permit was issued and was again successfully objected to by ICL and others on the grounds that it was still not sufficiently protective of public health. During the public comment period for the third version of this permit, both the Idaho Conservation League and EPA submitted comments with additional recommendations to protect public health. IDEQ failed to respond to these comments and also failed to incorporate these measures into this permit. In fact, the EPA Region 10 indicated that IDEQ did not reach out to EPA to discuss their comments and concerns. This third version of the permit was officially issued on June 17, 2022. On July 22, 2022, the Nez Perce Tribe, the Idaho Conservation League, and Save the South Fork Salmon officially submitted a petition administratively appealing the issuance of the permit. Perpetua attempted, unsuccessfully, to dismiss the appeal, and oral arguments are slated for spring 2023. The Forest Service has not participated in any of these proceedings.</p> <p>Had ICL and others not objected to the state's first draft air quality permit, the Forest Service could have assumed that this permit to construct was sufficiently protective of public health and the environment. Instead, as written, this flawed permit would have allowed Perpetua's mining activities to blanket the Operations Area Boundary with fugitive dust containing toxic levels of arsenic. This degree of arsenic contamination would have had significant impacts on National Forest lands and public resources, and would have been exceedingly difficult to remediate. To help address the remaining shortcomings of the third version of the permit, the Forest Service should require ambient air quality monitoring at the Operations Area Boundary and at several points along the public route through the SGP to Thunder Mountain. Ambient air quality monitoring at surface mines is not a novel concept. Several open pit surface mines across the West currently require ambient air monitoring, including the Bingham Canyon Copper Mine in Utah, and the Cripple Creek and Victor Gold Mine in Colorado. Any ambient air quality monitoring should be conducted according to a publically reviewable plan that is developed based on best industry practices.</p>	REG	This comment suggests that the Forest Service is deferring to state regulatory programs for the environmental analysis. This is not correct. The SDEIS clearly identifies the state regulatory programs that would apply to the Proposed Action and where the state has created certain environmental standards that would apply to the Project these have been included in the EIS. The Forest Service has not deferred the necessary hard look at the environmental impacts required under NEPA and has required Perpetua to provide separate environmental documentation to support the NEPA analysis separately from what they may prepare for the state agencies. An example of this is discussed in Section 4.3 of the SDEIS where separate air emission inventory and air quality impact modeling was required by the Forest Service to support its evaluation of the reasonably foreseeable impacts as required under NEPA. The Forest Service NEPA air impact evaluation included impacts from fugitive dust emission as well as off-site vehicle emissions.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	383	<p>4. Water Quantity</p> <p>Perpetua's Water Rights application is an entirely separate process from the NEPA process for the Stibnite Gold Project. In this case, the Forest Service recognized that Perpetua's use of the water rights could have negative effects on outstandingly remarkable values in the Wild and Scenic Main Salmon River. The Forest Service and several other parties are protesting specific water rights related to this application. We appreciate the Forest Service's involvement in this issue. We also believe that additional measures on the part of the Forest Service related to the development of alternatives and design features in the NEPA process could be used to avoid, minimize, and mitigate impacts for water resources.</p>	REG	Based on review of input from the public on the SDEIS, the Forest Service has included added mitigation measures in the Final EIS to address impacts to water resources that could be impacted by the SGP.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	384	<p>5. Summary</p> <p>While the state permitting is designed to be protective of the human environment, the Forest Service should view the state permitting process as a starting point and not the end point. Projects such as the SGP will have significant and permanent negative impacts on National Forest System lands. We recognize that the Forest Service has limited capacity to engage in state rulemaking and state permitting</p>	REG	The state permitting agencies are in regular communication with the Forest Service on their permitting activities and the Forest Service does intend to review the permit terms and conditions when they are ready to examine.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			processes. This is why it is critically important for the Forest Service to thoroughly review all state permits relevant to the SGP to ensure they comply with federal standards regarding protection of multiple uses and public resources. By utilizing a Supplemental SDEIS, we believe the Forest Service can utilize the NEPA process to conduct this review and make additional project improvements as needed so that public lands and public health are adequately protected.		
Jolie Drake	18929	2	Unfortunately, the antiquated General Mining Act of 1872 gives Perpetua (or anyone, foreign or domestic) the right to mine on Idaho land while paying zero royalties. However, this act does not also grant them the right to cause environmental damage or harm the recreational use and enjoyment of nearby areas. This SDEIS does not provide the breadth and granularity required to fully assess the risks and required mitigation for a project of this scope. Nor did the abbreviated comment period allow adequate time for a thorough enough review of a project of this magnitude.	REG	SDEIS Chapter 4 analyzed the potential Project effects on 23 classifications of environmental resources present in the Project vicinity. The Final EIS includes expanded discussion of mitigation measures per that analysis and public comments received on the SDEIS. The 75-day public comment period was deemed adequate for public review of the SDEIS.
Jolie Drake	18929	7	With all the environmental risks associated with the Perpetua mining project, and lack of sufficient federal oversight, we should not support nor allow this project to move forward. In spite of the 1872 mining act, there is recent precedent for denying a minerals mining permit. Last year, the federal government blocked the Twin Metals copper mine along the pristine Boundary Waters in northern Minnesota and in late 2020, the Pebble Mine gold mine project was denied by the U.S. Army Corps of Engineers because it could not adequately comply with Clean Water Act guidelines, thus they concluded "the proposed project is contrary to the public interest." I would propose that similar justification is equally warranted in this sensitive and unique habitat in Idaho.	REG	No further response required. General in nature or position statement.
Samuel Penney (Chairman)	19396	6	The Tribe is outraged that the Forest chose to proceed with the Modified Mine Plan as its Preferred Alternative. The Forest remains stubbornly resistant to embracing its legal duty to the Tribe because it will require denying Perpetua authorization to proceed with its Project. The Forest lacks authority to violate the Tribe's treaty rights and must deny the Project. On November 30, 2022, the White House issued a Presidential Memorandum on Uniform Standards for Tribal Consultation. That Presidential Memorandum builds on President Biden's January 26, 2021, Presidential Memorandum acknowledging foundational principles underlying the Nation-to-Nation relationship with tribes and reaffirming the United States' commitment to uphold treaty and trust responsibilities. The White House, in coordination with 17 federal agencies, including the United States Department of Agriculture ("USDA"), also released a new best practices report to integrate tribal treaty and reserved rights into agency decision-making processes. This report was developed in consultation with Tribal Nations and implements the agencies' Memorandum of Understanding Regarding Interagency Coordination and Collaboration for the Protection of Tribal Treaty Rights and Reserved Rights. An essential point raised by tribes in this report is that "[f]ederal agencies must give effect to treaty rights and should seek to safeguard them as agencies contemplate action," and "ensure that agency actions do not impair Tribes' ability to exercise those rights." The report complements Secretarial Order 3403: Joint Secretarial Order on Fulfilling the Trust Responsibility to Indian Tribes in the Stewardship of Federal Lands and Waters issued by USDA and the Department of Interior ("DOI") on November 15, 2021. The Joint Secretarial Order commits to ensuring that USDA and DOI and their component bureaus and offices are managing federal lands and waters in a manner that seeks to protect the treaty, religious, subsistence, and cultural interests of tribes.	REG	The Forest Service consideration of a mining application is required under U.S. Mining Law. As described in SDEIS Section 1.6.1, that consideration is to ensure that the proposed occupancy and use of National Forest lands is consistent with statutory and regulatory requirements plus ensure that measures are included that provide for the mitigation of environmental impacts and reclamation of surface disturbance. Selection of the 2021 Modified Mine Plan as the Preferred Alternative is consistent with the consideration of statutory and regulatory requirements along with the mitigation of environmental impacts including impacts to treaty rights as added to the revised EIS.
Samuel Penney (Chairman)	19396	20	1872 Mining Law and the Claims Validation Prerequisite for Occupancy The Forest's purpose and need statement is flawed because it assumes without proof or analysis that "Perpetua's proposed use of the surface of [National Forest System] lands" is "authorized by the U.S. mining law." The Forest Service may not simply assume that Perpetua has a "statutory" right to occupy National Forest System lands to extract valuable minerals, without evidence that Perpetua has met the statutory criteria to occupy the land. The SDEIS simply states that "the Forest Service's need for action [is] established by the agency's responsibilities under the locatable minerals regulations at 36 CFR Part 228, subpart A, and the General Mining Law of 1872, as amended" and that its review and approval of	REG	The Forest Service is not assuming the validity of the mining claims included in the SGP. The status of the mining claims for the area of the SGP is described in Section 4 and Appendix II of the 2021 Feasibility Report which was prepared in compliance with the National Instrument 43-101 of the Canadian Securities Administrators Standards (NI 43-101) for reporting mineral properties (M3, 2021). This report describes the mineralization at the SGP property and the location of mining claims within the property. This report was cited in the SDEIS and is part of the Project Record. This information has been reviewed by a qualified Forest Service mineral examiner and determined to be reliable.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>Perpetua’s proposed uses of federal land are authorized by the 1872 Mining Law and governed by the Forest Service’s hardrock mining regulations at 36 CFR Part 228 Subpart A. This is insufficient.</p> <p>In Center for Biological Diversity v. U.S. Fish and Wildlife Service, the Ninth Circuit Court of Appeals held that the Forest Service could not approve a mining operation on National Forest System lands without validating the mining claims that the mining operation will permanently occupy. “If a valuable mineral deposit has been discovered on a claim, a miner may occupy the claim for mining purposes. In the absence of a discovery of a valuable mineral deposit, Section 22 gives a miner no right to occupy the claim beyond the temporary occupancy necessary for exploration.” The Court agreed with the district court that the right of occupancy under the 1872 Mining Law requires that the claimant demonstrates as a statutory prerequisite, for each claim, the presence of valuable minerals on the claim. The Court further held that the mining regulations under Part 228A, Subpart A do not apply to unvalidated mining claims.</p> <p>Here, the Forest Service appears to violate the Ninth Circuit Court of Appeals’ holding. There is no evidence in the record validating the existence of valuable minerals on each of Perpetua’s mining claims. There is similarly no evidence in the record documenting that each millsite claim is associated with a valid mining claim, overlays nonmineralized ground, and otherwise meets the strict requirements of United States mining law. In fact, the number and location of Perpetua’s mill site claims along Meadow Creek (depicted in the figure below prepared by the Tribe) suggests that many mill site claims in this area may not be associated with a valid mining claim. Since there is no evidence in the record demonstrating that the Forest determined the validity of Perpetua’s mining claims, the Forest cannot presume that the mining regulations under Part 228A, Subpart A apply at this juncture and must do the requisite due diligence to determine claims validity and make those determinations available for Tribal and public review and comment in another SDEIS prior to issuing a decision on the Project.</p> <p>If the Forest cannot confirm that Perpetua’s mining claims are valid or determines that they are invalid, the Forest must evaluate Perpetua’s use and occupancy of National Forest System lands under Parts 251 and 261 regarding special use regulations under the Organic Act. The Part 251 regulations apply to occupancy and use of National Forest System lands. Under these regulations, the applicant must file a special use proposal with the District Ranger or Forest Supervisor having jurisdiction over the affected land. The Forest Service must then conduct an initial screening to determine whether the proposed use meets the “minimum requirements applicable to all special uses.” If the proposal passes this initial screening, the Forest Service must conduct a second level screening which requires, among other things, a showing that the proposed use is in the public interest. If the proposed use satisfies the Forest Service’s screening criteria, the Forest Service may grant a special use permit, but must include terms and conditions to “[m]inimize damage to scenic and esthetic values and fish and wildlife habitat and otherwise protect the environment,” among other requirements. The Forest Service must also “[o]therwise protect the public interest.” “The USFS will grant a special-use application submitted under Part 251 only if the proposed use complies with the applicable forest plan and ‘will not create an exclusive or perpetual right of use or occupancy’” or ‘involve disposal of solid waste or disposal of radioactive or other hazardous substances’ on forest lands.” Under the related Part 261 regulations, the Forest Service is also required to prohibit the destruction of cultural resources on public lands.</p> <p>Despite these requirements recently affirmed by the Ninth Circuit Court of Appeals in Center for Biological Diversity v. United States Fish & Wildlife Serv., the Forest Service states in the Stibnite Gold Project SDEIS Comment Response Table: “228A regulatory framework was applied pending additional guidance from counsel. No validity assessment of unpatented claims was incorporated per Forest Service practice.” Since the Forest Service has either failed to inquire as to whether all of the mining and millsite claims are valid for the Project or has failed to include the information it does have in the SDEIS, the administrative record does not show that the proposed facilities, uses, and associated operations are in fact authorized by United States mining law.</p>

Samuel Penney (Chairman)	19396	21	<p>Right-of-Way Requirements under FLPMA</p> <p>The Forest has also failed to comply with requirements for special uses on federal lands and rights of way under the Federal Land Policy and Management ("FLPMA") right of way ("ROW") provisions for the Project. At least three important potential substantive requirements flow from the FLPMA's ROW provisions. First, the Forest Service has a duty under Section 505(a) to impose conditions that "will minimize damage to scenic and esthetic values and fish and wildlife habitat and otherwise protect the environment."48 Second, Section 505(b) requires a Forest Service determination as to what conditions are "necessary" to protect federal property and economic interests, as well as "otherwise protect[ing] the public interest in the lands traversed by the rightof-way or adjacent thereto," and third, the Forest Service must ensure the ROW grants "do no unnecessary damage to the environment" and be "consistent with ... any other applicable laws." A grant of a ROW supporting other activities must satisfy all applicable treaties and laws, regulations and policies, including FLPMA, the Endangered Species Act, Organic Act, the National Forest Management Act ("NFMA"), National Historic Preservation Act, Clean Water Act, and Clean Air Act. It is not evident from the SDEIS that the Forest Service has complied with any of these requirements.</p>	REG	<p>As described in Section 1.7 of the SDEIS, the Forest Service is reviewing the 2021 MMP under the regulations pertaining to locatable minerals development on NFS lands. Part 36 CFR 228.3 defines mining operations as "<i>All functions, work, and activities in connection with prospecting, exploration, development, mining or processing of mineral resources and all used reasonable incident thereto, including roads and other means of access on lands subject to the regulations in this part, regardless of whether said operations take place on or off mining claims.</i>"</p> <p>Also discussed in Section 1.10.3.2 of the SDEIS, mining operations subject to 36 CFR 228 subpart A and not considered "special uses" subject to 36 CFR 251 Subpart B according to 36 CFR 251.50 (a).</p>
Samuel Penney (Chairman)	19396	22	<p>1.7 Federal Decision Framework</p> <p>The Tribe is concerned that the SDEIS discloses that resources and/or areas would not maintain or move towards Forest Plan desired conditions into the foreseeable future under the action alternatives. Further, Appendix A states that "[i]t is recognized that not all proposals would move towards or achieve desired conditions, goals, or objectives and there may be tradeoffs between moving towards or achieving these for one resource or another" which implies that the Project and its environmental impacts are acceptable consequences. The Tribe argues that any project or proposal must meet all relevant laws, regulations, and policies, not vice versa. The established regulations must not cater to or be amended to meet a proposed project. The Tribe recognizes there are tradeoffs in land management, however, when Forest Plan desired conditions, goals, objectives, standards, and guidelines are dismissed or amended to meet a proposal, they lose meaning, effectiveness, and adversely impact the federal trust responsibility of the Forest Service to the Tribe. Perpetua's mining Project does not align with the direction of the Forest Plans; it moves the Forest away from meeting desired conditions.</p> <p>The Tribe looks forward to the Forest's rationale for deviation from compliance in the decision document. The Payette and Boise National Forest Plans define guidelines "[a]s Forest Plan management direction, a guideline is a preferred or advisable course of action generally expected to be carried out. Deviation from compliance does not require a Forest Plan amendment (as with a standard), but rationale for deviation must be documented in the project decision document."</p>	REG	<p>Approving mining operations authorized by the 1872 Mining Law is different than any other proposed actions within the Forest. Most proposed actions originating within the Forest Service can be tailored to achieve certain future conditions, goals and objectives stated in the Forest Plans. However, mining operations are designed by the proponents around the constraints of natural site conditions, reasonably available methods of operation, and economics. Therefore, review and approval of mining operations on the NFS lands needs to consider what level of environmental protection is reasonable and feasible instead of forcing compliance with all Forest Plan goals or objectives.</p> <p>The 36 CFR 228A rules recognize that the U.S. mining laws confer a statutory right to enter NFS lands. The rules also recognize that mining operations can produce significant impacts to forest resources and the goal of the Forest Service rules and procedures is, "<i>where feasible</i>", to minimize adverse environmental impacts on the NFS surface resources. Rule 228.8 incorporates requirements for harmonizing operations with scenic values, maintaining and protecting fisheries and wildlife, and reclaim the surface disturbed by mining to "<i>practicable</i>" degrees. The Forest Service believes the 2021 MMP, as mitigated, complies with the intent of the 228A regulations.</p>
Samuel Penney (Chairman)	19396	23	<p>In Table 1.7-2 Key Permits, Approvals, and Regulation Compliance Likely Required, there is a permit missing. Under Idaho Department of Environmental Quality ("IDEQ") permits (on page 1-14), a Title V operating permit will be required once the 40 CFR 63 Subpart EEEEEEE – National Emission Standards for Hazardous Air Pollutants ("NESHAPs") for Gold Mine Ore Processing and Production Area Source Category units start up.</p>	REG	<p>The permit noted in the comment has been added to Table 1.7-2.</p>
Samuel Penney (Chairman)	19396	39	<p>The environmental baseline described in the SDEIS accounts for neither the Tribe's existing Clean Water Act lawsuit against Perpetua, nor EPA's ongoing discussions with Perpetua to address, through a potential CERCLA order, restoration of the Stibnite mine site as required under federal law. The Tribe's expectation of the CERCLA process is that remediation of the existing conditions will be undertaken comprehensively and site-wide regardless of whether mining operations were permitted, started and then stopped, or proceed to completion. Without this information, the Forest cannot accurately identify and disclose in the DEIS the environmental baseline conditions in the Project area.</p>	REG	<p>Section 1.3 of the SDEIS describes the CERCLA history of the site and the actions to be taken under the ASAOC. The SDEIS describes the CERCLA status of the SGP operations area at the time the EIS was prepared. To consider future legal outcomes would have been speculative. If the CERCLA status of the site changes before the Final EIS is released, those changes will be described in the document.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Samuel Penney (Chairman)	19396	42	Given that mining and storing 450 million tons of waste rock and tailings at the site cannot realistically, much less practically, be done without creating more environmental damage, the SDEIS should clearly have stated that the no action alternative with required remediation is the least damaging practicable alternative, and therefore the only alternative that the Corps can permit under Section 404 of the Clean Water Act.	REG	The USACE will select the least environmentally damaging practicable alternative (LEDPA) through their Section 404 permitting process. This was not available at the time the SDEIS was prepared.
Samuel Penney (Chairman)	19396	47	2.4.9 Environmental Design Features To protect air quality after the SGP begins operations, the Forest Service relies on the state of Idaho's monitoring and enforcement of the SGP air permit to construct ("PTC"). However, the state of Idaho lacks the robust compliance assurance, monitoring, and enforcement resources that will be necessary to inspect and regulate such a facility in a remote location and ensure the SGP is meeting permit conditions and not violating the National Ambient Air Quality Standards ("NAAQS"). The minimum inspection frequency required of the air permit is once every five years. Given the extraordinary level of fugitive emissions controls necessary to achieve 93.3% control, and the State's own acknowledgement that this level of control will be very challenging, a once every five years inspection frequency is woefully inadequate to ensure NAAQS compliance.	REG	The Final EIS includes information on dust monitoring at certain locations at the SGP to confirm the dispersion modeling results discussed in the SDEIS.
Samuel Penney (Chairman)	19396	50	Also in Table 2.4-12, there is a statement: "Dust abatement chemicals would be used in accordance with the applicable road maintenance Biological Assessment." There may be a potential conflict with meeting 93.3% dust control efficiency criteria on haul roads if use of dust abatement chemicals is limited.	REG	Use of dust abatement chemicals is part of the Project as proposed to meet the proposed dust control efficiency.
Samuel Penney (Chairman)	19396	55	Information Missing in the SDEIS Under NEPA's implementing regulations, "[w]hen an agency is evaluating reasonably foreseeable significant adverse effects on the human environment in an environmental impact statement and there is incomplete or unavailable information, the agency shall always make clear that such information is lacking. (a) If the incomplete information relevant to reasonably foreseeable significant adverse impacts is essential to a reasoned choice among alternatives and the overall costs of obtaining it are not exorbitant, the agency shall include the information in the environmental impact statement." Table 4.1-1 Incomplete and Unavailable Information in the DEIS provides a list of information that was not included in the DEIS but deemed relevant to reasonably foreseeable significant adverse impacts and essential to a reasoned choice among alternatives. The Forest, however, did not include with this Table, or anywhere in the DEIS, any explanation justifying the Agency's decision not to include this information in the DEIS because the overall cost of obtaining this information would be exorbitant. Without this justification, the Forest was required under NEPA to include all of the missing information identified in Table 4.1-1 in the DEIS. The SDEIS does not reference the DEIS or provide similar information on incomplete and unavailable information, leaving the inference that there no longer is incomplete or unavailable information deemed relevant to reasonably foreseeable significant adverse impacts and essential to a reasoned choice among alternatives. It is doubtful that this is the case, and regardless the SDEIS should have addressed this regulatory requirement.	REG	The 2020 DEIS table cited in this comment was not included in the SDEIS because the Forest Service addressed all of the listed items in that table with the information included in the SDEIS.
Samuel Penney (Chairman)	19396	70	CHAPTER 3 AFFECTED ENVIRONMENT 3.2.2.1 1872 Mining Law The statutory right to search for, develop, and extract mineral deposits on public-domain lands open to mineral entry was established by the General Mining Act of 1872 ("1872 Mining Law") and later legislation. These rights include the right to initially locate a mining claim and the right to reasonable access to the claim for further exploration, mining, or necessary ancillary activities, consistent with the Mining and Mineral Policy Act of 1970 and other applicable laws. As described elsewhere in this EIS, regulations at 36 C.F.R. 228 Subpart A apply to Forest Service regulation of surface use of National Forest System lands for locatable mineral operations. The relevant laws, regulations, and policies in the SDEIS fail to reference the Minerals and Geology Resources management direction of the Payette National Forest Land and Resource Management Plan and the Boise National Forest Land and Management Plan specifically the standards and guidelines, such	REG	The compliance of the SGP with the current Payette NF Plan and the Boise NF Plan is discussed in Section 1.7 of the SDEIS. This section states that both Forest Plans provide direction relevant to the 2021 MMP and its action alternatives. The approach taken for this discussion is not to describe all applicable Forest Plan components for the SGP but to identify those Forest Plan components that might need to be amended to allow the SGP to be consistent with the Forest Plans.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			as, but not limited to Standard MIST06 and Guidelines MIGU02, MIGU08, MIGU09, MIGU10, and MIGU11 in both Forest Plans.		
Samuel Penney (Chairman)	19396	71	The SDEIS needs to clearly explain how the Project will meet Forest Plan compliance. In Appendix A, the SDEIS states that “[t]he Plan submitted by Perpetua aligns with the forest-wide goals and objectives for the PNF and BNF as they relate to Minerals and Geology resources.” The SDEIS leaves out reference to each Forest Plan’s standards and guidelines for Mineral and Geology Resources. In doing so, the SDEIS does not explain how the Project aligns with Forest Plan direction or how the Project would meet these standards and guidelines. For example, the SDEIS fails to reference Guideline MIGU11 and does not show how it considers relocation, closure, changes in management strategy, alteration, or discontinuance for resources (e.g., soils, vegetation, wetlands, water quality, aquatic species, terrestrial species, etc.) that will be degraded or lost due to mine facilities or practices.	REG	<p>The compliance of the SGP with the current Payette NF Plan and the Boise NF Plan is discussed in Section 1.7 of the SDEIS. This section states that both Forest Plans provide direction relevant to the 2021 MMP and its action alternatives. The approach taken for this discussion is not to describe all applicable Forest Plan components for the SGP but to identify those Forest Plan components that might need to be amended to allow the SGP to be consistent with the Forest Plans.</p> <p>The SDEIS identifies those Forest Plan components that might need to be amended to allow the 2021 MMP to be consistent with the Forest Plans. The intention of this approach is that the 2021 MMP would apparently be consistent with all other Forest Plan components not needing to be amended.</p> <p>Impacts of the proposed mining operations to soils, vegetation, wetlands, water quality, aquatic species, terrestrial species etc. are each described and evaluated in separate sections of the SDEIS other than the Sections 3.2 and 4.2, Geologic Resources.</p>
Samuel Penney (Chairman)	19396	78	The SDEIS references Forest Service Manual 2840 Reclamation and includes the statement “[r]eclaimed areas may not always achieve desired conditions in the Forest Service management direction.” which appears to contradict the objectives and policies in FSM 2840. Under what circumstances and authorities can the Forest Service allow a proposed project to deviate from desired conditions? If the Forest cannot ensure that disturbed lands are reclaimed to a use that is consistent with long-term forest land and resource management plans, then the Forest should reject the Project.	REG	The SDEIS correctly describes the uncertainty in the outcome of future mine land reclamation activities related to the SGP. The 36 CFR 228A regulations that apply to this project include recognition of the inherent variability of reducing environmental effects of mining. Section 228.8, Requirements for Environmental Protection, paragraph (g) includes the modifier "where practicable" for the expected reclamation activities. FSM 2840 cites 36 CFR 228A as one of the authorities for the manual. The FSM 2840.3, Policy, paragraph 3 also states that "Reclamation requirements shall be those reasonable, practicable, and necessary to attain standards". The goals and objectives of the proposed 2021 MMP reclamation plan are discussed in Section 4.5.2 of the SDEIS as well as the predicted outcomes of the reclamation efforts. Impacts to vegetation resources are described in Section 4.10.2. The Forest Service believes that the reclamation activities included in the 2021 MMP are in compliance with the 36 CFR 228A rules.
Samuel Penney (Chairman)	19396	112	3.10 Vegetation The relevant laws, regulations, policies, and plans in the SDEIS need to include FSM 2070 Vegetation Ecology and statutes therein (e.g., FSM 2070.11), including reference to the Surface Mining Control and Reclamation Act of 1977 that “...directs the establishment on the mined areas, and all other lands affected, a diverse, effective, and permanent vegetation cover of the same seasonal variety native to the area of land to be affected and capable of self-regeneration and plant succession at least equal in extent of cover to the natural vegetation on the area...” The SDEIS should also note in Chapter 3.10.3 that the Payette and Boise Forest Plans not only provide a framework for analysis of impacts on vegetation, but they also outline management direction for vegetation (e.g., desired conditions, standards, and guidelines).	REG	The Surface Mining Control and Reclamation Act of 1977 applies to the regulation of coal mining and does not apply to hard rock mineral operations. The directly applicable Forest Service Manual to the SGP is FSM 2800 and its subparts. FSM 2817.21 describes the requirement for inclusion of reclamation of areas disturbed by mining operations and also states that, "Although improvement of surface resource conditions, above those existing prior to the mining operations or preparations for future use, are desirable goals, they cannot be forced on operators as an added cost." The Forest Service believes the reclamation and closure activities proposed by the 2021 MMP are consistent with the requirements of the 36 CFR 228A regulations and the applicable requirements of FSM 2800 and its subparts.
Samuel Penney (Chairman)	19396	134	Section 3.11.3, Clean Water Act, page 3-243. In February of 2022 the Corps adopted the pre-2015 rule and this no longer categorically excludes ephemeral features as jurisdictional waters and the General Condition 23(d) Stream Mitigation threshold changed to all losses of stream bed that exceed 3/100-acre. Although impact analysis has been completed and jurisdictional review by Corps is underway, the Tribe is unclear how this review will address impacts to WOTUS identified in the SDEIS. Would this increase the impacted acreage if adopted? The results of this review including (identification of acreage, full analysis and disclosure of impacts) need to be addressed in an addendum or supplement to the DEIS.	REG	The EIS analysis of impacted acreage is based on the USACE jurisdictional determination.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Samuel Penney (Chairman)	19396	143	Under relevant laws, regulations, policies, and plans, the SDEIS should reference Forest Service Manual 2840 Reclamation, specifically section 2841 which includes “[r]eclamation components for plans of operations: Forest Supervisors shall ensure the following administrative and environmental components are adequately addressed in each Plan of Operations when applicable:...[f]ish and wildlife habitat reclamation or mitigation.”	REG	Forest Service requirements associated with reclamation are described in SDEIS Table 2.4-12.
Samuel Penney (Chairman)	19396	162	<p>Wetlands</p> <p>As the SDEIS notes, there are numerous wetland resources identified in the Operations Area Boundary and adjacent areas throughout the analysis area. Wetlands provide important ecological functions for associated streams and rivers. Impacts to wetland and riparian areas are impacts to fisheries, wildlife, and vegetation habitat and therefore treaty rights and resources.</p> <p>Congress enacted the Clean Water Act (“CWA”) in 1972 to “restore and maintain the chemical, physical, and biological integrity of the Nation’s waters.” The CWA establishes several goals, including attainment and preservation of “water quality which provides for the protection and propagation of fish, shellfish, and wildlife...” To further its goals, the CWA prohibits “discharge of any pollutant” into navigable waters except in accordance with the CWA terms.</p> <p>The Corps issues permits for the discharge of dredged or fill material pursuant to section 404 and subject to the Corps’ and EPA’s 404(b)(1) Guidelines (“Guidelines”). Corps regulations governing the issuance of Section 404 permits declare that “[m]ost wetlands constitute a productive and valuable public resource, the unnecessary alteration or destruction of which should be discouraged as contrary to the public interest.” The Corps must ensure compliance with the 404(b)(1) Guidelines before issuing a permit. The Guidelines prohibit the permitting of any discharge of dredged or fill material: 1) if there is a practicable alternative to the proposed discharge, 2) if the discharge causes or contributes to violations of applicable state water quality standards, 3) if the discharge will cause or contribute to significant degradation of the environment, or 4) unless all appropriate steps have been taken to minimize potential adverse impacts. These factors both individually and cumulatively must be considered when evaluating the specific details of the 404 application.</p> <p>The Corps cannot authorize a discharge without “sufficient information to make a reasonable judgment as to whether the proposed discharge will comply with [the Section 404(b)(1)] Guidelines.” When a project is not “water dependent,” and the Project would fill “special aquatic sites,” including wetlands, the Corps’ regulations create a rebuttable presumption that there are practicable and environmentally preferable alternatives, and such alternatives are presumed to have less adverse impact unless “clearly demonstrated” otherwise. This substantive requirement mandates the Corps to select the least environmentally damaging practicable alternative). Pursuant to the Guidelines, no discharge of dredged or fill material shall be permitted if, among other things, a practicable alternative to the proposed discharge would have less of an adverse impact on the aquatic ecosystem. An alternative is practicable “if it is available and capable of being done after taking into consideration cost, existing technology, and logistics in light of overall project purposes.” Practicable alternatives include “activities which do not involve a discharge of dredged or fill material,” as well as “discharges of dredged or fill material at other locations” where such discharges would result in fewer impacts to the aquatic environment. The applicant has the burden of demonstrating that no feasible alternative exists, and the Corps must engage in a reasoned analysis of this issue. The Corps cannot blindly and uncritically accept an applicant’s study of alternatives and its assertions that no practicable alternative exists. Under the regulations, any “practicable” alternative to achieve the basic and overall project purposes must be determined to be cost effective, when viewed from the perspective of the industry as a whole. The financial circumstances of a particular applicant are not considered relevant if an alternative could be achieved practicably by a “typical” applicant. The preamble to the 404(b)(1) regulations states:</p> <p>“Our intent is to consider those alternatives which are reasonable in terms of the overall scope/cost of the proposed project. The term economic might be construed to include consideration of the applicant’s financial standing, or investment, or market share, a cumbersome inquiry which is not necessarily</p>	REG	No further response required. General in nature or position statement.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>material to the objectives of the Guidelines. We consider it implicit that, to be practicable, an alternative must be capable of achieving the basic purpose of the proposed activity.”</p> <p>But the least environmentally damaging practicable alternative need not be the least-costly, nor the most profitable. The regulations presume that less environmentally damaging alternatives are available to the applicant and practicable, unless the applicant clearly demonstrates otherwise. In the absence of such a clear showing, the Corps is required to deny the permit application.</p> <p>The Corps also cannot authorize any discharge of dredged or fill material that will cause or contribute to significant degradation of the waters of the United States. The “degradation or destruction of special aquatic sites, such as filling operations in wetlands, is considered to be among the most severe environmental impacts covered by the [] Guidelines.”</p> <p>To ensure the mandatory CWA requirements are satisfied, the Corps must evaluate the direct, secondary, and cumulative impacts of the activity on a number of resources. The EPA Guidelines require the Corps to make detailed factual determinations regarding the individual and collective effects associated with the discharge activity, and “no discharge of dredged or fill material shall be permitted which will cause or contribute to significant degradation of the waters of the United States.” “Findings of significant degradation related to the proposed discharge shall be based upon appropriate factual determinations, evaluations, and tests required by subparts B and G ..., with special emphasis on the persistence and permanence of the effects outlined in those subparts.”</p> <p>The Corps cannot issue a 404 permit if it “would be contrary to the public interest.” This requires the Corps to consider “the probable impacts” of a proposed project on “[a]ll factors which may be relevant to the proposal[,] including the cumulative effects.” “Evaluation of the probable impact which the proposed activity may have on the public interest requires a careful weighing of all those factors which become relevant in each particular case.”</p> <p>All factors which may be relevant to the proposal must be considered including the cumulative effects thereof: among those are conservation, economics, aesthetics, general environmental concerns, wetlands, historic properties, fish and wildlife values, flood hazards, floodplain values, land use, navigation, shore erosion and accretion, recreation, water supply and conservation, water quality, energy needs, safety, food and fiber production, mineral needs, considerations of property ownership and, in general, the needs and welfare of the people.</p> <p>The Corps must fully consider the impacts from the entire mine in making its public interest determination. “To require [the Corps] to ignore the indirect effects that would result from its actions would be to require it to wear blinders that Congress has not chosen to impose.” In addition to the above-analyzed cases, the Ninth Circuit has recognized the Corps’ duty to consider these impacts in order to ensure that issuance of the 404 permit is in “the public interest.” In <i>Ocean Advocates</i>, after finding that the Corps failed to consider the cumulative impacts from increased shipping traffic resulting from the issuance of a 404 permit for an oil refinery dock, the court noted that upon remand and consideration of these effects, “the Corps may impose conditions on the operation of permitted terminals at any time ‘to satisfy legal requirements or to otherwise satisfy the public interest.’ 33 C.F.R. § 325.4(a).”</p> <p>The 404(b)(1) Guidelines also prohibit the Corps from issuing a 404 permit “unless appropriate and practicable steps have been taken which will minimize potential adverse impacts of the discharge on the aquatic ecosystem.” Those seeking a 404 permit must mitigate the impacts of the proposed dredge and fill activities by “avoiding, minimizing, rectifying, reducing, or compensating for resource losses.” The purpose of the compensatory mitigation program is to “offset unavoidable impacts to waters of the United States authorized through” 404 permits.</p> <p>Mitigation is required for “significant resource losses which are specifically identifiable, reasonably likely to occur, and of importance to the human or aquatic environment.” These adverse effects to aquatic resource functions, whether direct or indirect, must be mitigated. Additionally, under NEPA, an EIS must: (1) “include appropriate mitigation measures not already included in the proposed action or alternatives,” and (2) “include discussions of:... Means to mitigate adverse environmental impacts (if not</p>		

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>already covered under 1502.14(f).” “All relevant, reasonable mitigation measures that could improve the project are to be identified, even if they are outside the jurisdiction of the lead agency or the cooperation agencies...”</p> <p>As part of reviewing and approving the mitigation plan, Corps regulations require that Perpetua provide “financial assurance” to cover mitigation costs: “(n) Financial assurances. (1) The district engineer shall require sufficient financial assurances to ensure a high level of confidence that the compensatory mitigation project will be successfully completed, in accordance with applicable performance standards...” “The rationale for determining the amount of the required financial assurances must be documented in the administrative record for either the DA permit or the instrument.”</p>		
Samuel Penney (Chairman)	19396	197	<p>4.9 Surface Water and Groundwater Quality</p> <p>According to the SDEIS, the West End pit is predicted to take 57 years to fill to approximately six feet below the level of where the predicted outflow from the pit lake to the surface water would be anticipated to spill over.380 In the event that water levels rise to the level near spill over, temporary water treatment is proposed to occur if needed; however, the unlined West end pit lake is predicted to receive groundwater inflow and produce groundwater outflow infuse connecting groundwater sources with persistent (at a minimum to Mine Year 112 where modeling was concluded) and elevated levels of antimony, arsenic, and mercury. The SDEIS does not clearly define whether the Project will be responsible for treatment of potential spillover events in perpetuity. In reference to Sugar Creek, which “is listed 303(d) category 5 for arsenic (primary contact recreation) and mercury (cold water aquatic, primary contact recreation, salmonid spawning) and receives water from West End Creek, the SDEIS does not cover whether impaired groundwater release from the West End Pit falls under the proposed IPDES permit for the Project or whether these effects have been modeled to infer the potential consequences on the downstream water quality standards of West End Creek, which is listed by IDEQ as fully supporting or good quality in categories 1 and 2 of §305(b) of the Clean Water Act (“CWA”).</p> <p>Under the 2022 U.S. District Court of Colorado decision, Stone v. High Mountain Mining Company, groundwater discharges from a settling pond into a navigable water of the United States fall under the CWA § 301 and 402 and therefore require a National Discharge and Elimination System (“NPDES”) permit for discharge of pollutants to surface waters via groundwater. The Project should be required to obtain an IPDES permit for the discharges of pollutants from the West End pit groundwater outflow to surface waterbody, West End Creek. The SDEIS and the SGP IPDES application does not reference obtaining an IPDES permit, monitoring requirements, or effluent limitations for this specific groundwater discharge coming from West End Pit seepage.</p>	REG	<p>SDEIS Section 4.8.2.2 indicates that the West End Pit lake is not expected to overflow.</p> <p>SDEIS Section 4.9.2.2 describes potential outflow of the West End Pit lake to groundwater and related effects on groundwater quality and surface water quality in West End Creek and Sugar Creek.</p>
Samuel Penney (Chairman)	19396	200	<p>The SDEIS states that the underdrain flows would be collected in a sump downstream of the toe of the buttress, monitored for water quality, then either discharged to Meadow Creek if underdrain water is not exceeding water quality standards or otherwise pumped to the ore processing facility, or sent to a contact water pond for either treatment and discharge or water used for the mill process. Because the underdrain collection of seepage is proposed to enter Meadow Creek at a point source as the first option, an IPDES permit with water treatment requirements, monitoring requirements, and effluent limitations for all constituents of concern (aluminum, antimony, arsenic, cadmium, copper, manganese, mercury, zinc, sulfate, and TDS) should be put in place and included in the SDEIS for review. The monitoring requirements and effluent limitations for all the above constituents previously mentioned above, are not made clear in the Stibnite Gold Project IPDES Permit Application. What conditions would the IPDES permit, if any, require? Would it be practicable to treat metals to meet State water quality standards? How frequent will the sump be monitored? How long will post-closure monitoring and/or treatment occur? These are fundamental questions left unanswered in the SDEIS. It is also unclear in the SDEIS on how the TSF Underdrain Internal Outfall will be routed to a treatment facility.</p> <p>It is assumed that the underdrain system will contain all seepage below the lower geosynthetic cover in the TSF; however, this assumption is unreasonable and it should not be assumed that because an underdrain system is in place that all seepage will be contained. The SDEIS does not account for the</p>	REG	<p>The underdrain flow is included in the EIS effects analysis as a discharge that meets Idaho water quality criteria, potentially following water treatment if it does not meet water quality criteria without treatment. Specific requirements of the IPDES permit are determined by IDEQ via its permitting process, but the completed IPDES would result in a discharge that meets State requirements.</p> <p>Monitoring of the discharge would be required until a determination was made that water treatment could be discontinued. The current estimate for this time period is approximately 40 years.</p> <p>Predicted water chemistry associated with the tailings storage facility is described in SDEIS Section 4.9.2.2 and was incorporated into the evaluation of water treatment methods.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			volume of seepage not collected by the underdrain system and thus fails to require this contaminated water allocated to the IPDES permit.		
Samuel Penney (Chairman)	19396	424	<p>APPENDIX A: Payette National Forest and Boise National Forest Land and Resource Management Plans Consistency Review and Amendments</p> <p>Perpetua's mining project does not align with the direction of the Forest Plans; it moves the Forest away from meeting desired conditions. The Forest acknowledges and justifies this in part in Appendix A of the SDEIS where it states: "[i]t is recognized that not all proposals would move towards or achieve desired conditions, goals, or objectives and there may be tradeoffs between moving towards or achieving these for one resource or another." The Tribe recognizes there are tradeoffs in land management, however, when Forest Plan desired conditions, goals, objectives, standards, and guidelines are dismissed or bent to meet a proposal, they lose meaning and effectiveness.</p> <p>The Forest Plan amendments waive or remove the time frame for resource impacts. How is it possible to waive a project's time frame (20 years) and stay true to the non-degradation intent of the Forest Plan components? What purpose do Forest Plan standards serve if they can so easily be bent or set aside?</p> <p>The Tribe is disappointed in the Forest's rationale in Table 1 for deviation from Forest Plan compliance. Perpetua will not be able to maintain or restore ecosystem integrity when the entire upper Meadow Creek watershed is permanently altered. Adverse impacts to surface water and groundwater quality and quantity will occur in perpetuity and thus will degrade Tribal resources.</p>	REG	The potential impacts to water resources caused by the Proposed Action and action alternatives are described in Sections 4.8 and 4.9 of the SDEIS. Impacts to Heritage Resources and Tribal Rights are described in Sections 4.17 and 4.24 of the SDEIS. Proposed changes to the PNF and BNF Forest Plans considered for the potential approval of the 2021 MMP as the Agency Preferred Alternative are described in Section 1.7 of the SDEIS.
Samuel Penney (Chairman)	19396	426	The Payette and Boise National Forest need to reinitiate Section 7 consultation with the Regulatory Services on the Payette and Boise Forest's Land and Resource Management Plans regarding the proposed Plan amendments. What is the status of Section 7 consultation for this? The Tribe would like to be involved through government consultation in this process. This proposed Project will have an adverse effect on ESA-listed fish and their habitat so the Forest must demonstrate (e.g., from monitoring results of projects below main spawning areas) during planning or consultation that similar projects have been implemented and sediment delivery to streams was avoided or minimized.	REG	<p>The Forest Service has conducted Section 7 consultation with the USFWS and NOAA Fisheries (referred to as the Services) regarding plant and animal species on the Endangered Species List that would be potentially affected by the Project. The Forest Service prepared a Biological Assessment and submitted it to the Services for their use in the Section 7 consultation process. The Services have accepted the Biological Assessment and the Services will each issue a Biological Opinion regarding the project effects on ESA-listed species and mitigation requirements.</p> <p>Section 7 consultation can be incorporated into government-to-government consultation.</p> <p>Project effects on ESA-listed fish species are described in SDEIS 4.12.2.</p> <p>Sediment monitoring in the Project's Operational Area would be required under an approved Water Resources Monitoring Plan.</p>
Samuel Penney (Chairman)	19396	429	<p>The 2003 NOAA Fisheries Biological Opinion for the Land and Resource Management Plan Revisions for the Boise, Payette, and Sawtooth (Southwest Idaho Ecogroup) National Forests ("SWIE LRMP") has the following Terms and Conditions: 2. To implement RPM #2, Maintain linkages between the SWIE LRMP and broad-scale restoration/recovery strategies, the Forest Service shall:</p> <p>In the Upper Salmon, South Fork Salmon, and Little Salmon River subbasins, not allow likely to adversely affect actions with adverse effects lasting three years or longer on ESA-listed anadromous fish species or their habitat prior to completion of the appropriate consultation framework document, unless informed or driven by recommendations from existing or new subbasin assessments or watershed analyses.</p> <p>There is no documentation in the Project record any existing or new subbasin assessments or recent watershed analyses for the upper EFSFSR, as required in the above-referenced 2003 BiOp for actions resulting in likely adverse effects lasting longer than three years. The Tribe accordingly requests that the Forest perform these requisite assessments and analysis and provide it for Tribal and public review and comment in a new SDEIS prior to initiating Endangered Species Act consultation on the Project and prior to issuing a final EIS or decision on the Project.</p>	REG	The documentation of the subbasin assessment as required by the 2003 Biological Opinion has been added to the project record.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			Have the default WCI values for this subbasin based on the best available data on functioning habitat conditions for ESA-listed fish within SFSR subbasin been revised within the Aquatic Conservation Strategy?		
John Rygh		20	To ensure protection of groundwater the State of Idaho would be required to set Points of Compliance. The Forest Service should be involved in this process as much as possible. Three points should be set; one on the East Fork South Fork Salmon River (EFSFSR) just above the confluence with Sugar Creek, one on Sugar Creek just above the confluence with the EFSFSR, and one on Meadow Creek just above the confluence with the EFSFSR. These should utilize paired wells (or isolated sampling intervals within one wellbore) to monitor both alluvial groundwater and bedrock groundwater. Corrective actions should be specified should threshold contaminate concentrations be exceeded.	REG	Idaho Cyanide Permits are prepared individually for each application and permit conditions and limits are based on the site-specific characteristics of the proposed operations, their operating and closure procedures, and the natural conditions at the project site. At the time this SDEIS was prepared the permit limits and requirements had not yet been established by IDEQ. This was clearly stated in the last sentence of the IPDES Permits and Cyanidation Permit subsection on page 4-224.

National Environmental Policy Act

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Responses
John Vander Woude (Representative)	7154	5	As a Representative and an Idahoan, I hope that you will consider my thoughts during the review process.	NEPA	No further response required. General in nature or position statement.
Judy Boyle (Representative, District 9, Seat B)	7158	4	The NEPA process has been robust and the Forest Service's decision to designate the 2021 MMP as the preferred Alternative signals to me that you too understand the benefits this project will have on Idaho should it be permitted.	NEPA	No further response required. General in nature or position statement.
Conway Ivey (Executive Chairman, Ivy Minerals, Inc.)	13274	10	This obstructive and lengthy approach conflicts with the public policy purposes of the National Environmental Policy Act and the Forest Service multiple use policy mentioned at the beginning of my letter. So, the USFS in coming to its decision should do the following; <ul style="list-style-type: none"> The USFS should let the facts guide their actions. In my 40 years in the mining industry I have never observed a proposed mining project that has undergone more analysis and review, that contains more environmental protections and mitigations, or that offers such an enormous opportunity to clean up historic environmental contamination that will otherwise impact the environment for decades or centuries. And all this for a region that needs jobs, needs infrastructure, and that is eager for the chance to help the United States achieve a domestic source of a critical mineral so that we are not dependent on China, Russia, or other unreliable sources. In short, the USFS should approve SGP because it has so many benefits, because it has so many protections and mitigations, and because it has been studied and analyzed for so long and in so much detail that any claim of unknowns and uncertainties is either ungenueine or reflects only those things that are unknowable for any project. I know the USFS will thoughtfully consider all viewpoints as it has for 7 years during this NEPA process, but as lead agency, it has to put facts first. <p>The Modified Mine Plan clearly fits within the four corners of the regulatory guidance and requirements of the National Environmental Policy Act and the Multiple Land Use Policy of the USFS.</p>	NEPA	The 2021 MMP utilizing the Burntlog Route is the Agency Preferred Alternative.
Snake River Fund	16536	3	Potential impacts from the Stibnite Gold Project extend far beyond the proposed 14,221 acre operational boundary and present concerns to all citizens living within or recreating upon the South Fork Salmon River watershed and the thousands of miles of river downstream.	NEPA	The geographic scope of effects was disclosed by the resource affected in Chapter 3 of the SDEIS. The geographic scope of effects differs by resource as these analysis areas are determined by setting meaningful bounds incorporating an area where the contribution of the alternatives is no longer quantitatively or qualitatively meaningful.
Hendrickson, Emily (President, Women's Mining Coalition)	17429	9	WMC understands that the Forest Service must remain impartial. However, NEPA requires agencies to disclose and give equal treatment to both the positive and negative impacts associated with a proposed action. The SDEIS and the Specialist Reports that augment the information in the SDEIS fully document beneficial impacts as well as the unavoidable or residual adverse impacts that would result from the	NEPA	A summary table of environmental impacts is found in Table 2.8-1. A reference to this table was added to the Final EIS Executive Summary section.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Responses
			<p>MMP. The Final EIS needs to discuss this information in a more evenhanded manner that does not inappropriately dwell on the adverse impacts while overlooking the beneficial impacts. Because no new information or different analyses are needed to disclose the full range of impacts associated with the SGP, this information can be synthesized and clarified in the Executive Summary in the Final EIS. This synthesis is mainly an editing task to ensure the Final EIS presents a more accurate and complete discussion of project impacts that is easier for the public to understand.</p> <p>A reader-friendly easy way to improve the Executive Summary in the Final EIS would be to add a table that briefly lists the beneficial and adverse environmental, economic, and social impacts that would result from development of the MMP and the mitigation measures that would eliminate or reduce adverse impacts. This table would facilitate the public's understanding of how the MMP will affect the environment, local communities, and other stakeholders. Rather than having to read the entire Final EIS, the public could use this table to obtain a quick overview of the project impacts.</p>		
Hendrickson, Emily (President, Women's Mining Coalition)	17429	25	<p>Judging from recently published opinion pieces and comments on the 2020 Draft EIS, certain project opponents are asserting that the 2019 Arizona Federal District Court's decision in Center for Biological Diversity et. al. v. U.S Fish and Wildlife Service et. al. (the "Rosemont" case) should be applied to the SGP. Their assertions are without merit because the ruling in Rosemont was decided based on the site-specific geological and land configuration facts at Rosemont. This decision cannot be extrapolated to other mineral deposits and proposed mining operations where the geologic conditions are not analogous to Rosemont.</p> <p>In Rosemont, the record before the District Court unequivocally documented that the lands proposed for the Rosemont Project's waste rock and tailings storage facilities were not mineralized and that mining claims had been located on these lands. Based on these specific facts, the District Court ruled that these mining claims were invalid. However, this decision cannot be simplistically exported to other mineral deposits and proposed mining projects where the site-specific facts are different. Because each mineral deposit is geologically unique, the correct mining claim and/or mill site configuration must be similarly site specific to accommodate the geologic facts. Because the on-the-ground situation at Rosemont is unique to Rosemont, the District Court's ruling is not a blueprint for any other proposed mining project. Consequently, the District Court's Rosemont opinion is not applicable to the SGP or to any other proposed mine because no two mines or mineral deposits are identical. The Ninth Circuit Court of Appeals ruling in Rosemont discusses the difference between mining claims and mill sites stating: "The Mining Law allows mining companies to occupy federal land on which valuable minerals have been found, as well as non-mineral federal land for mill sites..." Mill sites can be used for development rock and tailings storage facilities and other ancillary uses needed to support a mining operation. Figure 3.9-3 in the SDEIS "Stibnite Mining District Geology," clearly illustrates where mineralized zones are located at the Stibnite Mine. Perpetua is proposing to locate the tailings impoundment and associated embankment/buttruss on lands in the Meadow Creek drainage that are not mineralized. Mill sites could be located on these non-mineral lands pursuant to Section 42 of the Mining Law. As discussed in Sections 1.10.3.1 and 1.10.3.2 of the SDEIS, the Forest Service eliminated two alternatives from detailed analysis that pertain to the applicability of the Mining Law and the Forest Services' 36 CFR Subpart 228A surface management regulations for locatable minerals. These alternatives were likely suggested by project opponents who are seeking to force fit the Rosemont decision to the SGP. As explained above, the Rosemont case is a one-off judicial ruling that is confined to the site-specific geological facts at the Rosemont Project. Therefore, it is not applicable to the Stibnite mineral deposit – or to any other mineral deposit. The Forest Service has thus correctly decided to not evaluate these alternatives in detail in the SDEIS. The Final EIS should similarly dismiss these alternatives from further consideration.</p>	NEPA	No further response required. General in nature or position statement.
von Lindern, Ian (Founder, Terragraphics International Foundation)	17436	2	<p>Previous DEIS Comments: DEIS comments submitted by TIFO in 2020 focused on analyses regarding Contaminants of Concern (COC)s, specifically toxic metals. The comments emphasized the lack of transparency, material balances, and coherence in the document; and highlighted the resulting difficulties in determining the extent and disposition of toxic contaminants throughout the proposed alternatives. Because of these shortcomings it was not possible to develop comprehensive material balances and verify coherence. Rudimentary material balances were developed by TIFO, through reverse</p>	NEPA	Section 1.9 of the EIS states that the comments received on the 2020 DEIS were reviewed and considered as additional scoping input for the SDEIS preparation. These comments were analyzed in a content analysis process to develop public concern statements. Perpetua also reviewed the comments received on the 2020 DEIS and sought to respond to many of these comments by revising and resubmitting their Plan of Operations. This process produced the Modified Plan of Operations (ModPro2) submitted in October 2021, which then became the

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Responses
			<p>engineering of Midas Gold support documents. Tables supporting the detailed calculations and data sources were attached to TIFO's DEIS comments. The comments and Tables illustrated the lack of transparency that precluded objective analyses of potential health and environmental risks associated with the SGP.</p> <p>Unfortunately, the Forest Service did not respond to public comments on the DEIS before substituting a new Preferred Alternative developed by Perpetua. Perpetua and the Forest Service characterize the new Alternative as refining the DEIS in response to public comments, without providing specific responses. As a result, the SDEIS Alternative comparison is limited to two site ingress/egress transportation routes and the status of previous comments is unknown. The Forest Service ignored public comments and de facto allowed Perpetua to determine which public comments are relevant and implied that responses are inherent in the SDEIS revisions. The Forest Service did little to address the lack of transparency and coherence in the SDEIS, and the documents remain fatally flawed. The introduction of a new Alternative in the SDEIS necessitated repeating the reverse engineering analyses to estimate material balance calculations with a different combination of Midas Gold and Perpetua support documents. SDEIS material balances are summarized in Tables attached below. TIFO's 2020 comments and DEIS material balance support Tables are provided as supplemental material.</p>		<p>2021 MMP which constituted a revised Proposed Action for Forest Service review. Sections 1 and 2 of the ModPro2 document explain how the changes in the modified plan of operations is partly in response to comments received on the 2020 DEIS. Appendix A of the ModPro2 document shows the comparison of the action alternatives reviewed in the 2020 DEIS and the ModPro2 plan. Because the 2021 MMP contained substantial changes to the Proposed Action that are relevant to environmental concerns the Forest Service decided to prepare a SDEIS. Also, based on comments received on the 2020 DEIS and the effects of the 2021 MMP, the Forest Service revised the action alternatives considered in the SDEIS. A major change in the format of the SDEIS and the 2020 DEIS was that technical supporting information was moved from the EIS to supporting Specialist Reports. The authors of these reports reviewed the public concern statements derived from the 2020 DEIS comments which advised the authors of the specialist reports regarding content of those reports to be responsive to what was learned from the 2020 DEIS comments. Per 40 CFR § 1503.4(a) the Final EIS will respond to individual comments or groups of comments. The Final EIS will contain responses to the comments received on the SDEIS and concern statements summarizing comments on the DEIS.</p> <p>The commenter submitted quantitative re-evaluation of the chemical characterization data in the 2020 DEIS to prepare elemental material balances for the different ore and waste materials of the operations. However, the elemental material balances are not solely indicative of potential environmental effects or how these effects compare to existing regulatory limits and guidance. These elemental material balances are not typically used in NEPA analyses of proposed mining operations. This is because quantification and relocation of elemental masses may not be directly associated with physical environmental effects. For example, relocating a certain mass of elemental antimony from an open pit to a development rock storage facility is not as informative as the mineral form and concentration of the mineral that contains the element, and how mobile would the element be in the environment based on the whole rock chemistry and the proposed management plan for the development rock. The impact analyses included in the SDEIS do utilize typically acceptable data and methods to predict chemical impacts to environmental media and then compares these projected impacts to existing regulatory requirements and guidance.</p>
von Lindern, Ian (Founder, Terragraphics International Foundation)	17436	4	The Forest Service has also imposed extraordinary burdens on Public Reviewers by i) allowing Perpetua to submit the new Alternative in the SDEIS without considering and replying to Public Comments on the DEIS, and ii) failing to conduct objective independent analyses for key health and air quality analyses, by deferring to analyses conducted by SGP for the Idaho Department of Environmental Quality (IDEQ) Permit to Construct (PTC). This has required reviewers to revisit analyses based on the DEIS Alternatives, repeat those analyses for the new SDEIS Preferred Alternative, compare the differences, and comment on both documents and the comparison. Similarly, reviewing the air quality analyses required obtaining and critiquing much of the support material from IDEQ. TIFO requested an extension detailing these challenges on December 15, 2022 and received no response from the Forest Service (letter attached).	NEPA	The Forest Service released the SDEIS on October 28, 2022, and required that all comments be submitted by January 10, 2023. This was a 75-day public comment period which was 30 days longer than the required 45-day comment period. Per 40 CFR 1502.9(c) the Forest Service determined that a supplement to the DEIS was required because the new alternative contained substantial changes that were relevant to environmental concerns. Per 40 CFR § 1503.4(a) the Final EIS responds to individual comments or groups of comments. The Final EIS contains responses to the comments received on the SDEIS and concern statements summarizing comments on the DEIS. A criticism of the 2020 DEIS was that it included too much technical information making it too long and difficult to review. In response to this criticism the Forest Service provided most of the technical supporting information for the SDEIS in separate specialist reports that were made available at the same time as the SDEIS. The air quality impact analysis in the SDEIS was supported by air emissions inventory and impact modeling information that was independent from that prepared by Perpetua for the IDEQ PTC and is contained in the Air Resources Specialist Report. The Forest Service conducted its own air impact analyses and did not defer to the IDEQ impact analyses. For the convenience of the reviewers, the emissions information that was used by the IDEQ for the PTC was disclosed in the specialist report and compared to the emissions inventory information used for the SDEIS.
von Lindern, Ian (Founder, Terragraphics)	17436	5	Both the DEIS and SDEIS lack transparency and coherence. The USEPA defines transparency to "... ensure that the regulatory science underlying its actions is publicly available in a manner sufficient for independent validation." https://www.regulations.gov/document?D=EPA-HQ-OA-2018-0259-9322 . Coherence is the quality of being logical and consistent, or presented in a manner in which all the parts	NEPA	The SDEIS is a well-organized, comprehensive review of the characteristics and potential environmental effects of the action alternatives considered. All sources of information used in the SDEIS are clearly cited and the specialist reports supporting the SDEIS with important data were made available on the Forest Service project website at the same time as the SDEIS

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Responses
International Foundation)			fit together to form a united whole. Neither document meets these criteria. Key data and analyses are contained in obscure, and often unavailable, references. With regard to COCs, neither overall productions figures, nor any material balances are provided. Determining the contaminant quantities, potential chemical forms and toxicity through the proposed immense mining operations and complex metallurgical processes requires tedious reverse engineering.= Various support documents were used to develop rudimentary COC material balances for both the DEIS and SDEIS. These accountings are used below to demonstrate specific health and environmental concerns with DEIS and SDEIS, and the insufficiency of the Forest Service analyses. It is not possible, in the time allotted with the available reference material, for an independent reviewer to assess the consistency and accuracy of the assertions made regarding COCs throughout DEIS or SDEIS.		itself. The important chemistry information for the ore and waste rock to be mined and their potential to release COCs is fully discussed in Sections 3.3, 3.5, 3.8, 3.9 of the SDEIS. The projected impacts of these COCs on environmental media are fully disclosed and discussed in the corresponding sections of Chapters 4 and 5 of the SDEIS. Where appropriate, these COC impacts are compared with applicable regulatory standards and requirements for the receiving media including ambient air, surface water, and ground water.
von Lindern, Ian (Founder, Terragraphics International Foundation)	17436	10	The Forest Service has never responded to public comments alleging the insufficiencies of the Alternatives in the DEIS. Those DEIS Alternatives were demonstrated to be fatally flawed by rejection from IDEQ. The Forest Service avoided making that determination by electing to provide no response, ignore the Public Comments, and narrowed the SDEIS analyses by substituting and selecting a new Preferred Alternative as suggested by Midas/Perpetua.	NEPA	Section 1.9 of the SDEIS states that the comments received on the 2020 DEIS were reviewed and considered as additional scoping input for the SDEIS preparation. These comments were analyzed in a content analysis process to develop public concern statements. Perpetua also reviewed the comments received on the 2020 DEIS and sought to respond to many of these comments by revising and resubmitting their Plan of Operations. This process produced the Modified Plan of Operations (ModPro2) submitted in October 2021, which then became the 2021 MMP which constituted a revised Proposed Action for Forest Service review. Sections 1 and 2 of the ModPro2 document explain how the changes in the modified plan of operations is partly in response to comments received on the 2020 DEIS. Appendix A of the ModPro2 document shows the comparison of the action alternatives reviewed in the 2020 DEIS and the ModPro2 plan. Because the 2021 MMP contained substantial changes to the Proposed Action that are relevant to environmental concerns, the Forest Service decided to prepare a supplemental draft EIS. Also, based on comments received on the 2020 DEIS and the effects of the 2021 MMP, the Forest Service revised the action alternatives considered in the SDEIS. A major change in the format of the SDEIS and the 2020 DEIS was that technical supporting information was moved from the EIS to supporting specialist reports. The authors of these reports reviewed the public concern statements derived from the 2020 DEIS comments which advised the authors of the specialist reports regarding content of those reports to be responsive to what was learned from the 2020 DEIS comments. Per 40 CFR § 1503.4(a) the Final EIS responds to individual comments or groups of comments. The Final EIS contains responses to the comments received on the SDEIS and concern statements summarizing comments on the DEIS.
von Lindern, Ian (Founder, Terragraphics International Foundation)	17436	21	However, as noted above, exposure estimates cannot be developed, as the link to the electronic support documents cited by the Forest Service cannot be accessed.	NEPA	Supportive documents (e.g., resource specialist reports, air modeling reports, fisheries baseline and modeling reports, water baseline and modeling reports, etc.) for the SDEIS were made available on the Forest Service project website at the same time as the SDEIS. Where reviewers requested additional information to review, the Forest Service did respond by making the information available.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	15	V. MANY SERIOUS AND UNRESOLVED CONCERNS ABOUT THE PROJECT ANALYSES WARRANT A SUPPLEMENTAL SDEIS. CEQ regulations provide: NEPA regulations must ensure that the environmental information is available to public officials and citizens before decisions are made and before actions are taken. The information must be of high quality. Accurate scientific analysis, expert agency comments, and public scrutiny are essential to implementing NEPA. "If a [DEIS] is so inadequate as to preclude meaningful analysis, the agency shall prepare and circulate a revised draft ." 40 C.F.R. § 1502.9(a) (1978). The SDEIS is riddled with data gaps, inaccurate description of the current environmental conditions, missing but available baseline information, among other concerns, which require revising and/or supplementing the SDEIS to comply with NEPA.	NEPA	No further response required. General in nature or position statement.
Bonnie Gestring (Northwest	17634	16	A. The SDEIS improperly relies on inaccurate or incomplete baseline data. To take the required "hard look" under NEPA, an EIS must describe the environmental baseline of the	NEPA	As stated in 40 CFR 1502.15 "The environmental impact statement shall succinctly describe the environment of the area(s) to be affected or created by the alternatives under

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Responses
Program Director, Earthworks) and seven others			<p>areas to be affected. 40 C.F.R. § 1502.15. An accurate baseline is “essential” to an informed analysis. 40 C.F.R. § 1502.21(b). Baseline conditions are necessary to “determine what effect the project will have on the environment” and thus to comply with NEPA. “Without establishing the baseline conditions which exist. before [a project] begins, there is simply no way to determine what effect the [project] will have on the environment and, consequently, no way to comply with NEPA.” An agency cannot rely on post-approval surveys, studies, or mitigation as a substitute for suitable baseline information. For example, courts have held that the Forest Service violates NEPA when it approves a mine exploration project without gathering baseline groundwater hydrology information to assess impacts of drilling before approving a project. While it may be permissible in some circumstances for an agency to estimate baseline conditions—instead of conducting actual measurements—by using data from a similar area, computer modeling, or some other method, the agency’s method “must be based on accurate information and defensible reasoning.”</p> <p>As shown throughout many sections of these comments, the Forest Service failed to gather and utilize adequate baseline data—data which is available or readily attainable. The Forest Service must correct these errors by gathering and utilizing up-to-date, accurate baseline data, and must issue a revised or supplemental SDEIS for public comment.</p>		<p>consideration. The descriptions shall be no longer than is necessary to understand the effects of the alternatives. Data and analyses in a statement shall be commensurate with the importance of the impact, with less important material summarized, consolidated, or simply referenced.” Baseline data was gathered and described as presented in each of the resource sections in Chapter 3 of the SDEIS. If baseline conditions were summarized due to the vast amount of data, the additional description was provided in the associated resource specialist report or other supporting documents that were also made available on the Forest Service project website with the SDEIS. The Affected Environment sections are within Chapter 3 of the SDEIS. The Forest Service believes that the baseline data used in the SDEIS is sufficient to describe the reasonably foreseeable environmental effects of the alternatives.</p>
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	22	<p>Instead of rushing ahead to approve Perpetua’s mine, the Forest Service should take the time to resolve these uncertainties, or should at least disclose these uncertainties and properly factor them into the SDEIS and its analyses.</p> <p>C. There are several instances of missing or incomplete information that are relevant to the foreseeable impacts and essential to a choice among the alternatives.</p> <p>NEPA’s purpose is “to foster excellent action,” and the “NEPA process is intended to help public officials make decisions that are based on an understanding of environmental consequences, and take actions that protect, restore, and enhance the environment.” 40 C.F.R. § 1500.1(c) (1978). To this end, an EIS must “provide full and fair discussion of significant environmental impacts.” Id. at 1502.1 (1978).</p> <p>NEPA requires that “environmental information is available to public officials and citizens before decisions are made and before actions are taken.” Id. at 1500.1(b) (1978). In an EIS, an agency must explain its methodology and results, and include its baseline studies as an appendix for the public to review.</p> <p>Information disclosed during the NEPA process “must be of high quality.” “Accurate scientific analysis, expert agency comments, and public scrutiny are essential to implementing NEPA.” As the Ninth Circuit has explained:</p> <p>Congress wanted each federal agency spearheading a major federal project to put on the table, for the deciding agency’s and public’s view, a sufficiently detailed statement of environmental impacts and alternatives so as to permit informed decision making. The purpose of NEPA is to require disclosure of relevant environmental considerations that were given a “hard look” by the agency, and thereby to permit informed public comment on proposed action and any choices or alternatives that might be pursued with less environmental harm.</p> <p>“[T]he very purpose of NEPA’s requirement that an EIS be prepared for all actions that may significantly affect the environment is to obviate the need for speculation by insuring that available data is gathered and analyzed prior to the implementation of the proposed action.” “NEPA requires that the agency provide the data on which it bases its environmental analysis.” NEPA, thus, requires transparency and placing the high-quality information the agency relied on before the public, before approving a project. This is true of supposedly confidential information too. As set forth in many sections in these comments, the SDEIS and its supporting documents rely/depend upon missing, incomplete, confidential, low quality, and inaccurate information. The Forest Service must, therefore, gather, consider, and disclose to the public important and high quality information about the Stibnite</p>	NEPA	<p>Any uncertainties were disclosed in the specific resource section in Chapter 4 of the SDEIS. The associated resource reports and supporting documents (baseline reports, modeling reports, etc.) were cited in the SDEIS and provided on the Forest Service project website along with the SDEIS.</p> <p>As noted in Section 3.1.1 of the SDEIS, the analysis areas vary by resource or resource use, depending on geographic extent of the resource or use and the extent of the potential effects of the SGP. The analysis areas may be larger or smaller than the SGP area, utilizing administrative or natural boundaries, based on potential effects on the resource.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Responses
			<p>Gold Project, the proposed alternatives, and their environmental effects in a supplemental or revised SDEIS and release it for public comment before rushing ahead to approve the Project.</p> <p>Additionally, in determining whether an EIS fosters informed decision-making and public participation, courts consider not only the content of an EIS, but also its form. The NEPA document “is where the [agency’s] defense of its position must be found.” To provide a “full” and “fair” discussion of environmental effects, an agency must address issues “up front” and cannot “cobble together a ‘hard look’ from various other analyses.”</p> <p>Here, even when information is purportedly available, much of it is incomprehensible, or extremely burdensome to find and use. Commenters hired multiple experts to review the SDEIS, who had to spend significant time cobbling together critical information the Forest Service relied upon in reaching its conclusions. The Forest Service must make all information available in a form suitable for public review as part of a supplemental or revised SDEIS released for public comment.</p> <p>D. The limited temporal and geographic scales render the analyses inadequate. “[A]n agency has the discretion to determine the physical scope used for measuring environmental impacts,” so long as its choice represents a reasoned decision and is not arbitrary. Similarly, an agency’s discretion to determine the temporal scope of its NEPA analysis requires the agency to consider the relevant factors and provide a rational connection between the facts found and the choice made. An agency must offer a “reasonable justification for why it drew the line where it did.”</p> <p>As set forth throughout these comments, the Forest Service arbitrarily constrained the temporal and/or geographic scope of its effects analysis to omit disclosure and evaluation of potential significant effects caused by the Stibnite Gold Project. For example, as discussed in more detail later in these comments, data collected to model baseline conditions is limited to small areas of the mine site and are spatially-biased. See infra.</p>		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	28	<p>NEPA requires preparation of a supplemental EIS if there are “significant new circumstances or information relevant to environmental concerns and bearing on the proposed action or its impacts.” 40 C.F.R. § 1502.9(c)(ii) (1978).54</p> <p>1. Department of Defense grant A significant new development occurred on December 19, 2022, when the Department of Defense announced \$24.8 million in grant funding for the Stibnite Gold Project, stating that: The DPA Investments Program will provide \$24.8 million to Perpetua to complete environmental and engineering studies necessary to obtain a Final Environmental Impact Statement, a Final Record of Decision, and other ancillary permits. Perpetua will perform this study work related to its Stibnite-Gold Project in central Idaho through 2024.(emphasis added).</p> <p>A similar press release by Perpetua Resources further emphasizes the development of essential information related to the SGP, including environmental baseline data monitoring, environmental and technical studies, as provided by new grant funding, announced on December 19, 2022:</p> <p>Under the funding agreement, Perpetua may request reimbursement for certain costs incurred over 24 months related to environmental baseline data monitoring, environmental and technical studies and other activities related to advancing Perpetua’s construction readiness and permitting process for the Stibnite Gold Project. (emphasis added)</p> <p>These environmental and engineering studies, which the DoD press release says Perpetua will perform through 2024, and are deemed “necessary to obtain a Final Environmental Impact statement,” must be provided for public review and comment in the NEPA process.</p>	NEPA	The Final EIS includes a discussion of the DoD grant which was announced after the SDEIS was released. The Forest Service understands the grant funds are for environmental and engineering work leading to a ROD. The Forest Service is not aware that this work will result in new information relevant to environmental concerns or bearing on the Proposed Action or its impacts to necessitate another SDEIS.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	75	<p>B. The purpose and need are unreasonably narrow An agency violates NEPA when it “define[s] its objectives in unreasonably narrow terms.” “A purpose and need statement will fail if it unreasonably narrows the agency’s consideration of alternatives so that the outcome is preordained.”</p>	NEPA	Section 1.6.1 of the SDEIS is an accurate statement of the Forest Service’s Purpose and Need and meets the intent of the purpose and need as outlined in 40 CFR 1502.13 because the agency is responding to a plan of operations submitted by an external proponent. The Forest Service must comply with regulations governing the use of surface resources for operations authorized by the United States mining laws on National Forest System lands under 36 CFR

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Responses
			<p>One obvious way for an agency to slip past the strictures of NEPA is to contrive a purpose so slender as to define competing “reasonable alternatives” out of consideration (and even out of existence). The federal courts cannot condone an agency’s frustration of Congressional will. If the agency constricts the definition of the project’s purpose and thereby excludes what truly are reasonable alternatives, the EIS cannot fulfill its role. Nor can the agency satisfy the Act.</p> <p>While the Forest Service is permitted to take the applicant’s purposes into consideration, it cannot draft a narrow purpose statement that restricts the consideration of alternatives to one motivated by private interests. “[A]n applicant cannot define a project in order to preclude the existence of any alternative sites and thus make what is practicable appear impracticable.” Federal courts have routinely found that NEPA prevents federal agencies from effectively reducing the discussion of environmentally sound alternatives to a binary choice between granting and denying an application.</p> <p>Here, the Forest Service defined its objectives in unreasonably narrow terms, and as a result, failed to consider other reasonable alternatives and proposes reaching a preordained conclusion in violation of NEPA. The SDEIS states, with respect to the Forest Service’s purpose and need:</p> <p>1.6.1 Purpose and Need for Federal Action The Forest Service’s purpose is to consider approval of Perpetua’s proposed use of the surface of NFS lands in connection with operations authorized by the U.S. mining law as first described in the Plan submitted September 2016, then refined in 2019 (Brown and Caldwell 2019a), and further modified in 2021 as the 2021 MMP (Perpetua 2021a). The Forest Service’s need for action is to ensure that the proposed occupancy and use of NFS lands is consistent with statutory and regulatory requirements. For purposes of this environmental analysis, the agency is assuming the proposed uses would be able to be authorized under existing regulatory authorities. However, the agency will need to evaluate the eventual applications for rights of way to make a final determination.</p> <p>The need for the action is to: Consider approval of Perpetua’s 2021 MMP for development of the SGP to mine gold, silver, and antimony deposits that, where feasible, would minimize adverse environmental impacts on NFS surface resources; and ensure that measures are included that provide for mitigation of environmental impacts and reclamation of the NFS surface disturbance.</p> <p>SDEIS at 1-8. Elsewhere, the SDEIS describes the Forest Service’s purpose and need as: The Forest Service’s purpose is to consider approval of the Plan to mine and process gold, silver, and antimony from deposits at the mine site in central Idaho for commercial sale. The purpose of the proposed SGP is consistent with Congress’ declaration in the Mining and Mineral Policy Act of 1970 (Public Law 91-631 as amended through Public Law 106-193).</p> <p>The Forest Service’s need for action is established by the agency’s responsibilities under the Locatable Minerals regulations at 36 CFR 228 Subpart A, which were promulgated under authority granted by the Mining Law of 1872 (Mining Law) (30 USC 22 et seq.) and the Organic Administration Act of 1897 (16 USC 478, 482, and 551). These regulations require that all locatable mineral prospecting, exploration, development, mining and processing operations, and associated means of access, shall be conducted in a manner that minimizes adverse environmental effects on NFS surface resources. SDEIS at A-12–A-13. See also A-22, A-29.</p> <p>First, the Forest Service’s focus on the general need to support mineral development under the 1970 Mining and Mineral Policy Act is misplaced. That Act, which merely notes general principles, creates no controlling statutory mandate on the agency. Instead, the Forest Service’s primary mandate is to protect the forest from destruction and depredations under the 1897 Organic Act. The agency’s guiding congressional mandate regarding the national forests is “to regulate their occupancy and use and to preserve the forests thereon from destruction.” 16 U.S.C. § 551. Yet, as discussed throughout these comments, the SGP would be inconsistent with numerous and important aspects of the Payette and Boise Forest Plans and other environmental laws and standards, would adversely affect public resources,</p>		<p>228, subpart A. These regulations require that the Forest Service respond to parties who submit a proposed plan of operations for approval to conduct operations authorized by the United States mining laws on National Forest System lands for part or all of their planned actions including mining, mineral processing, and uses reasonably incident thereto. In accordance with 36 CFR 228.5, the submittal of Perpetua’s proposed mining plan of operations requires the Forest Service to consider whether to approve the proposed mining plan of operations or to require changes or additions necessary to meet the purpose of the regulations for locatable mineral operations.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Responses
			<p>would restrict or eliminate uses and rights enshrined in treaties with the Nez Perce Tribe, and would otherwise significantly degrade forest resources.</p> <p>Instead of focusing the purpose and need on fostering mining, the Forest Service should focus on its authorities and duties under the Organic Act, the CWA, ESA, NFMA, NEPA, and other applicable laws and regulations. This way the Forest Service could consider alternatives and mitigation to Perpetua’s full-scale mine, including alternatives already proposed and/or considered in earlier comments and agency documents, such as: a cleanup/remediation first alternatives; different mining method alternatives, like underground mining; different processing methods; different facility locations; different water management.</p> <p>Second, the Forest Service’s assertion in the purpose and need statement that for “purposes of this environmental analysis, the agency is assuming the proposed uses would be able to be authorized under existing regulatory authorities,” and that it will evaluate later whether Perpetua’s proposal could be authorized, also violates NEPA because it unreasonably limits the alternatives the Forest Service considered. SDEIS at 1-8 (emphasis added). By making the assumption that all of Perpetua’s proposed activities would be authorized, the Forest Service is considering only two very similar alternatives— each of which authorizes the full suite of mining Perpetua has proposed in the manner the company proposes doing them. To credibly evaluate the purpose and need for this Project and associated features of it, the entire section needs to be rewritten following determination of the legal status of Perpetua’s claims and other asserted rights.</p>		
Giles, Robert (Mayor McCall, ID)	17834	1	Except for the Social and Economic Specialist Report, the City of McCall is again mostly excluded from the analyses as was the case in the DEIS. As previously stated in our first comment letter (attached and resubmitted with this letter) general references to McCall are made in many narrative sections but no impacts were specifically analyzed for our community even though we are the largest population center in Valley County and will be impacted a multitude of ways that are spelled out below. We believe this is an error on the part of Forest Service that, should the Forest Service approve the proposed mine, needs to be corrected by conducting additional supplemental analyses to provide complete disclosure of the impacts to the public, and provide appropriate information for the consideration of mitigation measures, required by the National Environmental Protection Act, prior to the issuance of the Final EIS and draft Record of Decision.	NEPA	Section 4.21.2.2 of the SDEIS describes Project effects to tourism, recreation economy, infrastructure, and public services including McCall. Increased road usage associated with the Project is described in Section 4.16.2.2 with Project effects on recreational usage described in Section 4.19.2.2 of the SDEIS.
Giles, Robert (Mayor McCall, ID)	17834	8	The Forest Service should address the impacts of mine traffic and displaced recreational traffic in a second supplemental DEIS.	NEPA	Increased road usage associated with the Project is described in Section 4.16.2.2 of the SDEIS with Project effects on recreational usage described in Section 4.19.2.2 of the SDEIS. The SDEIS notes the potential for reduced recreational access along routes utilized by the Project, but notes that there are alternative recreational locations to the affected routes.
Lynn Oliver	18565	2	The supplied story map for Perpetua's 2021 Modified Mine Plan and Supplemental EIS was outstanding. It sets a new standard for public participation in the NEPA process and this methodology should be incorporated in all future Forest Service projects.	NEPA	No further response required. General in nature or position statement.
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	6	Including an estimated financial assurance amount and mechanism, the disclosure of which is particularly important in this project given the long-term water management needs at the site (including post-closure).	NEPA	The calculation of reclamation costs and estimated financial assurance amounts and mechanisms would be based on the final approved mine and reclamation plan in the ROD.
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	40	Financial Assurance According to the DSEIS, calculation of the initial bond amount would be completed following the Record of Decision (ROD) when enough information is available to adequately and accurately perform the calculation. ⁴¹ EPA continues to recommend that the FEIS provide a more specific discussion of the estimated financial assurance amount and mechanism, particularly given the water management needs at the site (including post-closure). This would provide a basis for evaluating whether the planned reclamation and closure activities would be effective (funded) in the event of a bankruptcy or compliance issues. Other mining EISs have included financial assurance estimates that comport with the draft reclamation and closure plans and acknowledge that the final financial assurance would be	NEPA	The calculation of reclamation costs and estimated financial assurance amounts and mechanisms would be based on the final approved mine and reclamation plan in the ROD. That bond amount would be specified in a subsequent Forest Service decision following the ROD.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Responses
			determined after the ROD. For example, see the Donlin Gold Project EIS, the Haile Gold Project EIS, and the Northmet Project EIS. This level of disclosure is also important for the SGP. Failure to obtain sufficient financial assurance at the Stibnite Mine Site in the past has resulted in significant, unaddressed contamination at the Site. If not for the NEPA process, there would be no public disclosure of financial assurance estimates. We understand that draft estimates are currently available.		
Small, Nathan (Chairman, Fort Hall Business Council, Shoshone-Bannock Tribes)	18903	1	The Shoshone-Bannock Tribes (Tribes) have reviewed the available materials presented in the Stibnite Gold Project Supplemental Draft Environmental Impact Statement (Project SEIS) and offer the following comments regarding the overall impact of the Project and associated environmental concerns addressed as technical comments. As this communication includes both generally applicable comments on the Project's impacts to the Tribes and technical comments, please consider the context of both comments and when making the revisions please indicate how the comments were considered and if changes were made to the document when publishing the final document and record of decision.	NEPA	No further response required. General in nature or position statement.
Small, Nathan (Chairman, Fort Hall Business Council, Shoshone-Bannock Tribes)	18903	7	The purpose of NEPA is to require federal agencies to produce a "detailed statement" for "major federal actions significantly affecting the quality of the human environment" that must include analysis and description of impacts to a variety of environmental categories (i.e. water, air, socioeconomic, etc.). Basically, the federal agency is required to take a "hard look" at the Project and issue a decision document based on a reasonable range of alternatives. However, when an agency takes a 'hard look' at a mine plan of operations through a NEPA document the decision space is frustratingly narrow; to the extent where an agency cannot choose a 'no action' alternative or tell a mining company that mining is not in the public interest, regardless of impacts. In essence, the NEPA document becomes a vehicle to permit a mining activity that allows a private company to maximize profits through environmental deterioration and is subsidized by the people with the most connection to the landscape. From this perspective, the NEPA and 1872 mining laws are in direct conflict and should be resolved through regulation or other mechanisms. For example, a reasonable range of alternatives would include requirements to comply with existing Forest Plans, complete backfilling of pits, developing waste storage on private lands, avoiding tailing impoundment facilities, etc.	NEPA	The federal agencies involved in the EIS have responded to their regulatory requirements to objectively review the Proposed Action and consider whether to approve the 2021 MMP as submitted or any alternatives considered in detail in the Final EIS (Section 1.6 of the SDEIS). The development and review of alternatives that were considered is described in Section 2.2 of the SDEIS. Changes to the General Mining Law of 1872 are outside of the scope of this project as these are acts of Congress. Regulation changes or rulemaking cannot be decided with this analysis and subsequent decision as they are outside of the purpose and need of this project and require a separate rulemaking process.
Small, Nathan (Chairman, Fort Hall Business Council, Shoshone-Bannock Tribes)	18903	17	The tailings impoundment facility is located on unpatented mining claims, even though there is no intention to actually mine in that location; while this Project seems to gloss over this fact it is not the only issue with the location or design of the tailing impoundment. The Project actually creates a fish passage barrier, while removing other barriers; resulting in no net gains for passage and perpetual barriers due to the constituents associated with the tailings impoundment. There aren't many options to create sustainability from an inherently non-renewable enterprise, but creating a problem from the beginning is far from demonstrating good stewardship of public resources. In the end, the location of the tailing impoundment appears to be an effort to off-load a long-term waste storage facility on public lands and avoid perpetual maintenance of these contaminants. The Tribes request a complete evaluation and formal opinion on the legality of the 'millsite' areas that will be used to permanently occupy public lands and expand the 'mining' area by thousands of additional acres with little to no oversight; this opinion should be conducted by an objective agency counsel with knowledge of current mineral law in the 9th Circuit and included in the Final EIS and Record of Decision.	NEPA	The Forest Service has completed a review of the mining claims associated with the proposed project and included that review in the project record.
Small, Nathan (Chairman, Fort Hall Business Council, Shoshone-Bannock Tribes)	18903	21	All comments submitted on the DEIS that have not been addressed in the SDEIS and/or mine plan modifications should be considered as valid comments on the SDEIS.	NEPA	Section 1.9 of the SDEIS states that the comments received on the 2020 DEIS were reviewed and considered as additional scoping input for the SDEIS preparation. These comments were analyzed in a content analysis process to develop public concern statements. Perpetua also reviewed the comments received on the 2020 DEIS and sought to respond to many of these comments by revising and resubmitting their Plan of Operations. This process produced the Modified Plan of Operations (ModPro2) submitted in October 2021, which then became the 2021 MMP which constituted a revised Proposed Action for Forest Service review. Sections 1 and 2 of the ModPro2 document explain how the changes in the modified plan of operations is partly in response to comments received on the 2020 DEIS. Appendix A of the ModPro2 document shows the comparison of the action alternatives reviewed in the 2020 DEIS and the ModPro2 plan. Because the 2021 MMP contained substantial changes to the Proposed Action that are relevant to environmental concerns the Forest Service decided to prepare a SDEIS.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Responses
					Also, based on comments received on the 2020 DEIS and the effects of the 2021 MMP, the Forest Service revised the action alternatives considered in the SDEIS. A major change in the format of the SDEIS and the 2020 DEIS was that technical supporting information was moved from the EIS to supporting specialist reports. The authors of these reports reviewed the public concern statements derived from the 2020 DEIS comments which advised the authors of the specialist reports regarding content of those reports to be responsive to what was learned from the 2020 DEIS reviews. Per 40 CFR § 1503.4(a) the Final EIS responds to individual comments or groups of comments. The Final EIS contains responses to the comments received on the SDEIS and concern statements summarizing comments on the DEIS.
Michael Gibson (Trout Unlimited), Aaron Lieberman (Idaho Outfitters & Guides Association), Garret Visser (Idaho Wildlife Federation)	18903	2	In addition to requiring a reasonable range of alternatives, NEPA requires agencies to analyze direct, indirect, and cumulative impacts on “ecological...aesthetic, historic, cultural, social, or health” 40 CFR § 1508.1(g)(1) (1978). It is difficult for the public to analyze these impacts on a variety of topics due to a number of areas lacking in specificity, errors or discrepancies. The Forest Service should take the time to correct these errors in order to give the public better insight into the direct, indirect, and cumulative impacts of a project of this magnitude.	NEPA	The specific concerns included in this comment are responded to in other comment/resource categories. No further response required here. General in nature or position statement.
Deantha Skibinski, Executive Director, Alaska Miners Association	18899	6	<p>Redeveloping, Remining, and Restoring a Problematic Legacy Mine Site</p> <p>The SGP entails remining and reprocessing historic mine wastes that contain residual gold and antimony that can be economically recovered, and remining other mine wastes that do not contain valuable minerals and placing them in engineered containment facilities to isolate them from the environment. Both remining activities are important environmental restoration measures that will remove legacy materials from area streams (primarily Meadow Creek) where they are leaching arsenic, antimony and other contaminants into the watershed. The remining components of the MMP and the recovery of antimony from some of the legacy mine wastes are precisely the type of remining activity that recent critical minerals policies have identified as a potential source of critical minerals.</p> <p>On February 24, 2021, President Biden issued Executive Order 14017 (EO 14017) “On America’s Supply Chains.” EO 14017 directed the Secretaries of Commerce, Energy, Defense, and Health and Human Services to complete a supply chain review in 100 days and specified that the Secretary of Defense must prepare “a report identifying risks in the supply chain for critical minerals.”</p> <p>The June 2021 report “Building Resilient Supply Chains, Revitalizing American Manufacturing, and Fostering Broad-Based Growth,” which is the 100-day Supply Chain Review Report prepared in response to EO 14017, is directly relevant to the SGP because this report explicitly requires the Secretaries to evaluate reprocessing mine wastes as a viable source of critical minerals. As a remining and reprocessing project that will recover the critical mineral antimony from legacy mine wastes, the SGP illustrates the viability of the concept in the 100-Day Report that critical minerals could be recovered from certain legacy mine wastes.</p>	NEPA	<p>No further response required. General in nature or position statement.</p> <p>The Forest Service’s consideration of the Project on the basis of its ability to produce gold, silver, and antimony is described in SDEIS Section 1.6 as the Project’s Purpose and Need.</p>
Joseph Pietri	19062	18	<p>Perpetua plans to expand its exploration.</p> <p>Would that not require a new DEIS? New exploration increases risks of Fire, Water contamination and Hazardous material cleanups. Will Peretua be held responsible and accountable for all incidents related to their work? Perpetua plans to expand its exploration.</p> <p>Would that not require a new DEIS?</p> <p>New exploration increases risks of Fire, Water contamination and Hazardous material cleanups.</p>	NEPA	The proposed future development drilling activities are described in Section 2.4.6.1 of the SDEIS and the potential impacts are incorporated in the document. Future development drilling in concert with these descriptions would be adequately covered under NEPA by this EIS. Any significant changes in future development and exploration drilling from what is described in the Final EIS would be considered for additional NEPA review before approval.
Kira Tenney	19247	1	I am concerned that the proposed Stibnite Gold project would result in significant negative impacts to local and regional economies, community coherence and resilience, water resources, fish and wildlife, public safety, and the interconnected ecosystems within the watershed. As experts have provided data	NEPA	The specific concerns included in this comment are responded to in other comment/resource categories. No further response required here. General in nature or position statement.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Responses
			and information that support the costs of this project would far outweigh the benefits and the SDEIS has not provided the data and information required by NEPA (namely that relevant information will be made available to the public who also play a role in both the decision-making process and the implementation of that decision),		
Kira Tenney	19247	4	Finally, the SDEIS stated an incorrect description of the existing environment, included overstated benefits, had missing information, alternatives, and analysis (which were particularly outlined in comments that requested a SDEIS), made unreasonable assumptions, and included contradictory statements and claims. Legally, based on law such as “Accordingly, the Forest Service must take a ‘hard look’ at the environmental impacts of the Stibnite Gold Project, which means that the agency’s decision must not rely ‘on incorrect assumptions or data in an EIS.’” Native Ecosystems Council v. U.S. Forest Service, 418 F.3d 953, 964 (9th Cir.2005), further research and more accurate reporting of data and analysis for public review is needed.	NEPA	The specific concerns included in this comment are responded to in other comment/resource categories. No further response required here. General in nature or position statement.
Kira Tenney	19247	5	Additionally, the permitting process has been repeatedly delayed as Midas Gold (now Perpetua Resources) has repeatedly failed to provide accurate and timely information, and made repeated and fundamental changes to the mine plan midway through the NEPA process. This changing of plans indicates that there will be continued changes made by Perpetua, that the public would not be able to review as part of and required by NEPA. The public needs to be provided with truthful and accurate information. Would the USFS stand behind in a court of law the accuracy of all statements provided in the SDEIS? While neither Perpetua nor the SDEIS contractor is legally obligated to provide accurate, truthful, and complete information, NEPA clearly requires the USFS to stand behind the information in the SDEIS as accurate, truthful, and complete.	NEPA	The Forest Service has approved the information used to prepare the SDEIS.
Kira Tenney	19247	17	4. Forest Service Commitment to Best Available Science These stand out in the guiding Principles of the United States Forest Service: - We use the best scientific knowledge in making decisions and select the most appropriate technologies in the management of resources. This report does not include the best scientific knowledge and therefore is insufficient for comment. This SDEIS and the DEIS do not use the best scientific knowledge and needs to be updated as such.	NEPA	The Forest Service has approved the information used to prepare the SDEIS.
Zack Waterman (Northern Rockies Conservation Director)	19317	7	We believe that in order for the “hard look” standard of NEPA to be met, the Forest Service must consider additional alternatives, incorporate missing information and analysis necessary to make an informed decision among alternatives, and better consider impacts to eligible, suitable, and congressionally designated Wild & Scenic Rivers, as well as opportunities to mitigate those impacts. Please provide this analysis as a part of a revised SDEIS and allow adequate time for public review. Included with this letter is an attachment with the signatures of thousands of river advocates from across the nation – each of whom formally requests the Forest Service conduct additional analysis on this Stibnite Gold Project prior to the issuance of a Final Environmental Impact Statement.	NEPA	40 CFR 1502.14 states that an EIS must evaluate reasonable alternatives to the Proposed Action. Reasonable alternatives are those that respond to the Purpose and Need, are technically and economically feasible, and potentially reduce environmental effects to at least one resource, as described in Section 2.2.2 of the SDEIS. Potential impacts to Wild and Scenic Rivers was presented in Section 4.23.2.2 and 4.23.2.3 of the SDEIS.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	55	"Significant issues are those which are used to formulate alternatives to the Proposed Action and to develop mitigation measures." Please provide additional information from chapter 2 about which issues were used to develop which alternatives and mitigation measures, particularly in the 2021 MMP.	NEPA	The Proposed Action (2021 MMP) is not necessarily formulated around the selected issues for the EIS analysis because it was prepared separately and earlier than the SDEIS. The proponent revised their Proposed Action after public comments on the DEIS to reduce new surface disturbance and anticipated environmental impacts. As no additional mining alternatives were identified by the Forest Service that would reduce mining related impacts further, another mining alternative was not included. However, an alternative transportation route that met the Purpose and Need and potentially would reduce surface disturbance was carried forward as the Johnson Creek Route Alternative. The rationale for inclusion of the Johnson Creek Route Alternative is described in Section 2.5 of the SDEIS (see Table 2.5-1). Where mitigation measures were identified in the SDEIS, the issue driving the need for the mitigation measures are identified, see Section 4.8.3 for examples of this.

Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	56	Issues and indicators identified are not consistently used throughout the summary tables, the affected environment or the environmental consequences. While all the resource issues and their indicators should be made consistent with the other sections, it is particularly problematic in Tribal Rights and Interests, Wetlands and Riparian Resources, Access and Transportation. Please review how issues and indicators are used in the whole SDEIS, and make the list here consistent with lists in Chapter 4 sections and with various areas of Chapter 2.	NEPA	The issues and indicators in Table 2.8-1 have been made consistent with the issues and indicators cited in other sections of the Final EIS.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	57	"NEPA regulations require the agency to identify and eliminate from detailed study those issues that are not significant or that have been covered by prior environmental review, to narrow the scope of the analysis. Reasons for eliminating issues from detailed study include when the issues are related to the following: •General opinions or position statements not specific to the Proposed Action; •Items addressed by other laws, regulations, or policies; •Items not relevant to the potential effects of the Proposed Action, or otherwise outside the scope of this analysis; and/or, •Items that have no or negligible effects. " Please provide a citation for this list.	NEPA	Edit has been made. At the end of the first sentence in the first paragraph of Section 1.10.3 added the following citation "(CEQ Guidance Regarding Scoping, 4-30-81)."
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	60	" Executive Orders " Recommend clarifying that this issue was also not considered in detail because it is an opinion or position statement not specific to the Proposed Action.	NEPA	Sufficient reason for the Forest Service action with regards to Executive Orders is found in the last sentence of Section 1.10.3.3. The requested edit will not be made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	64	"The No Action Alternative provides an environmental baseline for comparison of the action alternatives. Under the No Action Alternative, the mining, ore processing, and related activities under the action alternatives, including removal of legacy materials, would not take place. However, existing, and approved activities (i.e., approved exploration activities and associated reclamation obligations) would continue. " It may be helpful to add a sentence clarifying ASAOC activities to this paragraph. Also, approved exploration activities are not guaranteed to continued; please change "would" to "could".	NEPA	Edit has been made. In the second paragraph of Section 2.2.3, beginning with "No Action Alternative -", in the third sentence inserted "work under the ASAOC and" before "approved exploration". In the same sentence, changed "would continue" to "could continue".
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	83	Issues and indicators identified are not consistently used throughout the summary tables, the affected environment or the environmental consequences. While all the resource issues and their indicators should be made consistent with the other sections, it is particularly problematic in Tribal Rights and Interests, Wetlands and Riparian Resources, Access and Transportation. Please review how issues and indicators are used in the whole SDEIS, and make the list here consistent with lists in Chapter 4 sections and with various areas of Chapter 1.	NEPA	The issues and indicators in Table 2.8-1 have been made consistent with the issues and indicators cited in other sections of the Final EIS.
Meg FitzMaurice	19329	5	It is clear that SGP will create unavoidable and irreversible environmental, social, and economic risks, many of which are not addressed, lack information and/or a detailed review in the SDEIS. The USFS is required through the NEPA (National Environmental Policy Act) to stand behind the information provided in the SDEIS as accurate and complete. Is the USFS willing to stand behind the accuracy and completeness of this document? I would not.	NEPA	The Forest Service has approved the information used to prepare the SDEIS.
Jon Robison	19330	14	I also note that there may have been a miscalculation with the deadline of January 10. For other projects, day 1 of the comment period begins the day after a project is posted in the Federal Register. If this is the case, the Forest Service should reopen the comment period.	NEPA	Per 40 CFR 1506.11(a), the minimum time periods set forth are calculated from the date of publication of the notice that an EIS is available in the FEDERAL REGISTER.
Jon Robison	19330	15	I am including by reference all scoping, DEIS and SDEIS comments submitted by the Idaho Conservation League and the Nez Perce Tribe.	NEPA	Section 1.9 of the SDEIS states that the comments received on the 2020 DEIS were reviewed and considered as additional scoping input for the SDEIS preparation. These comments were analyzed in a content analysis process to develop public concern statements. Perpetua also reviewed the comments received on the 2020 DEIS and sought to respond to many of these comments by revising and resubmitting their Plan of Operations. This process produced the Modified Plan of Operations (ModPro2) submitted in October 2021, which then became the 2021 MMP which constituted a revised Proposed Action for Forest Service review. Sections 1 and 2 of the ModPro2 document explain how the changes in the modified plan of operations

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Responses
					is partly in response to comments received on the 2020 DEIS. Appendix A of the ModPro2 document shows the comparison of the action alternatives reviewed in the 2020 DEIS and the ModPro2 plan. Because the 2021 MMP contained substantial changes to the Proposed Action that are relevant to environmental concerns the Forest Service decided to prepare a SDEIS. Also, based on comments received on the 2020 DEIS and the effects of the 2021 MMP, the Forest Service revised the action alternatives considered in the SDEIS. A major change in the format of the SDEIS and the 2020 DEIS was that technical supporting information was moved from the EIS to supporting specialist reports. The authors of these reports reviewed the public concern statements derived from the 2020 DEIS comments which advised the authors of the specialist reports regarding content of those reports to be responsive to what was learned from the 2020 DEIS reviews. Per 40 CFR § 1503.4(a) the Final EIS responds to individual comments or groups of comments. The Final EIS contains responses to the comments received on the SDEIS and concern statements summarizing comments on the DEIS.
Ruth Lewinski	19378	3	<p>1.0 Inappropriate Response of Public Comments from Previous Proposals Renditions of the Stibnite Gold Mine (SGM) Project have been discussed in Valley County for over a decade. In 2020, I submitted a personal comment for the DEIS, with questions particular to sections disclosed in that document. I never received a response in any kind from the Forest Service prior to the Preferred Alternative proposed by Perpetua (2022). Mine is amongst thousands of public comments that brought forward concerns. To me, this process lacks transparency and diminishes the direct impacts known to the public at this time. My understanding of the NEPA process is limited, but I understand it to be a review process during which the Forest Service and Federal Administration prioritize and acknowledge concerns rather than a private agency determining the appropriate interpretation and response. At this time, as my own concerns have not been addressed, it appears that the SGM has limited public review and is being pushed forward with undue risk and potential to harm without proper NEPA protocol.</p> <p>COMMENT: Prior comments have not been adequately responded to by the US Forest Service in regard to public concern for the proposed Stibnite Gold Mine Project. Please note, my comments for the 2020 DEIS were also submitted at this time.</p>	NEPA	Section 1.9 of the SDEIS states that the comments received on the 2020 DEIS were reviewed and considered as additional scoping input for the SDEIS preparation. These comments were analyzed in a content analysis process to develop public concern statements. Perpetua also reviewed the comments received on the 2020 DEIS and sought to respond to many of these comments by revising and resubmitting their Plan of Operations. This process produced the Modified Plan of Operations (ModPro2) submitted in October 2021, which then became the 2021 MMP which constituted a revised Proposed Action for Forest Service review. Sections 1 and 2 of the ModPro2 document explain how the changes in the modified plan of operations is partly in response to comments received on the 2020 DEIS. Appendix A of the ModPro2 document shows the comparison of the action alternatives reviewed in the 2020 DEIS and the ModPro2 plan. Because the 2021 MMP contained substantial changes to the Proposed Action that are relevant to environmental concerns the Forest Service decided to prepare a SDEIS. Also, based on comments received on the 2020 DEIS and the effects of the 2021 MMP, the Forest Service revised the action alternatives considered in the SDEIS. A major change in the format of the SDEIS and the 2020 DEIS was that technical supporting information was moved from the EIS to supporting specialist reports. The authors of these reports reviewed the public concern statements derived from the 2020 DEIS comments which advised the authors of the specialist reports regarding content of those reports to be responsive to what was learned from the 2020 DEIS reviews. Per 40 CFR § 1503.4(a) the Final EIS responds to individual comments or groups of comments. The Final EIS contains responses to the comments received on the SDEIS and concern statements summarizing comments on the DEIS.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	246	The SDEIS does not adequately address the potential impacts that the Stibnite Gold Project will have on the FCRNRW, IRAs, Recommended Wilderness Areas and the Chilcoot Peak RNA. Both mine-related use and public motorized access use of the newly constructed portion of the Burntlog Route will exacerbate the negative effects on these special areas and the Forest Service should drop this alternative. The Forest Service should prepare a supplemental SDEIS to re-assess the potential impacts the Stibnite Gold Project will have on these special areas and develop additional measures to avoid, minimize and mitigate the remaining impacts.	NEPA	<p>Per 40 CFR 1503.4 the agency preparing the final environmental impact statement shall assess and consider comments. Possible responses to the comments include supplementation, improvement, or modification of the analyses based on the comments. The Final EIS will include changes made in response to the comments received. The regulations at 40 CFR 1502.9(c)(1) provide guidance on when a supplement to a draft or final environmental impact statement is required.</p> <p>The analysis of impacts to the FCRNRW, IRAs, recommended Wilderness Areas, and the Chilcoot Peak RNA were presented in Section 4.23 of the SDEIS as well as the Special Designations Specialist Report that was made available on the Forest Service project website along with the SDEIS.</p>
Bonnie Gestring (Northwest Program Director,	17634	305	<p>S. Terrestrial Wildlife</p> <p>1. The Forest Service (FS) did not provide a useful summary of the changes between DEIS and SDEIS in relation to wildlife (or most every other resource) which impeded our review of the effects to wildlife</p>	NEPA	Section 1.9 of the SDEIS states that the comments received on the 2020 DEIS were reviewed and considered as additional scoping input for the SDEIS preparation. These comments were analyzed in a content analysis process to develop public concern statements. Perpetua also reviewed the comments received on the 2020 DEIS and sought to respond to many of these comments by revising and resubmitting their Plan of Operations. This process produced the

Earthworks) and seven others			The project was originally analyzed in a DEIS in 2020. In response to the FS request for public comments, ICL and others provided an extensive analysis of project effects. In October 2022, the FS released a SDEIS. The FS made little effort to provide a comparison of changes between the draft and supplement EIS. The FS did not acknowledge ICL's original concerns, and did not show how the concerns were addressed. This lack of information and transparency does not meet the intent of the NEPA.		Modified Plan of Operations (ModPro2) submitted in October 2021, which then became the 2021 MMP which constituted a revised Proposed Action for Forest Service review. Sections 1 and 2 of the ModPro2 document explain how the changes in the modified plan of operations is partly in response to comments received on the 2020 DEIS. Appendix A of the ModPro2 document shows the comparison of the action alternatives reviewed in the 2020 DEIS and the ModPro2 plan. Because the 2021 MMP contained substantial changes to the Proposed Action that are relevant to environmental concerns the Forest Service decided to prepare a SDEIS. Also, based on comments received on the 2020 DEIS and the effects of the 2021 MMP, the Forest Service revised the action alternatives considered in the SDEIS. A major change in the format of the SDEIS and the 2020 DEIS was that technical supporting information was moved from the EIS to supporting specialist reports. The authors of these reports reviewed the public concern statements derived from the 2020 DEIS comments which advised the authors of the specialist reports regarding content of those reports to be responsive to what was learned from the 2020 DEIS reviews. Per 40 CFR § 1503.4(a) the Final EIS responds to individual comments or groups of comments. The Final EIS contains responses to the comments received on the SDEIS and concern statements summarizing comments on the DEIS.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	377	<p>AA. Connected Actions associated with the long-distance transport of minerals, namely antimony concentrate, from the mine site to locations for processing are not identified or analyzed.</p> <p>As described in 40 CFR 1508.25, scope consists of the range of actions, alternatives, and impacts to be considered in an environmental impact statement. The scope of an individual statement may depend on its relationships to other statements (Secs.1502.20 and 1508.28). To determine the scope of environmental impact statements, agencies shall consider three types of actions, three types of alternatives, and three types of impacts. They include: (a) Actions (other than unconnected single actions) which may be: 1. Connected actions, which means that they are closely related and therefore should be discussed in the same impact statement. Actions are connected if they: (i) Automatically trigger other actions which may require environmental impact statements. (ii) Cannot or will not proceed unless other actions are taken previously or simultaneously. (iii) Are interdependent parts of a larger action and depend on the larger action for their justification.</p> <p>The description of traffic associated with the project is briefly addressed at page 2-21 through 2-22, but the subsequent analysis provided under the impact topic of Access and Transportation in chapters 3 and 4 inappropriately narrows the analysis area to exclude most of state highway. In fact, the analysis should continue until the mine associated traffic becomes commingled with other interstate traffic, which would be the juncture with I-84 to the south and either the Port of Lewiston or I-90 to the north. Because the "destination" for additional processing is in fact not located at the terminus of Warm Lake Road with SH-55, but rather some further distance to be accessed most likely through interstate travel, the long-distance transportation and processing should be disclosed and analyzed. This is particularly true if the processing of antimony is intended to occur in Mexico or Oman. In such a case, the export of a nationally important mineral to another country for processing should also be described in the socioeconomic section of the document. Alternatively, if the intent is to transport the antimony concentrate to a domestic smelter, those air quality impacts of the smelting process should be included as connected actions.</p> <p>Perpetua Resources anticipates that compost (and potentially other soil amendments) will be imported to the Project site and applied to GM and YPP Till to improve their suitability. It proposes to import 13,850 tons of compost (RCP, p. 352) from dairy or feedlot operations (composted manure), which would be temporarily placed in stockpiles around the facility. The transport of this material would be a connected action, and its transport should be analyzed in the SDEIS.</p>	NEPA	The transportation impact analyses area in the Final EIS as described in Section 3.16.2 includes SH 55 from Cascade to McCall. However, the Transportation Baseline Study (HDR 20171) considered a larger analysis area including SH 55 at Cascade south to I-84 and SH 55 to New Meadows and US 95 from New Meadows north to Grangeville. The current analysis area and analysis has been deemed sufficient and the long-distance transport of minerals, namely antimony concentrate, from the mine site to locations for processing are identified and analyzed.
Leah K. Corrigan	19000	2	<p>The purpose and need is unreasonably narrow</p> <p>The purpose and need for the project is defined very narrowly, in a manner that precludes consideration of reasonable alternatives to the proposed action. The Forest Service used the Stibnite Gold Project plan</p>	NEPA	Section 1.6.1 of the SDEIS is an accurate statement of the Forest Service's Purpose and Need and meets the intent of the purpose and need as outlined in 40 CFR 1502.13 because the agency is responding to a plan of operations submitted by an external proponent. The Forest Service must comply with regulations governing the use of surface resources for operations

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Responses
			of operations as the basis for determining the purpose and need, and developed the action alternatives in the plan based on the plan of operations. This approach precluded the Forest Service from analyzing a reasonable range of alternatives to the proposed action (see Section III) that would allow access to public lands to search for minerals consistent with US mining laws, while minimizing adverse environmental impacts to a much greater extent than any of the alternatives in the DEIS. The purpose and need should be defined more broadly to include restoring and maintaining the health of the Salmon River and its tributaries, and the fisheries that the river supports.		authorized by the United States mining laws on National Forest System lands under 36 CFR 228, subpart A. These regulations require that the Forest Service respond to parties who submit a proposed plan of operations for approval to conduct operations authorized by the United States mining laws on National Forest System lands for part or all of their planned actions including mining, mineral processing, and uses reasonably incident thereto. In accordance with 36 CFR 228.5, the submittal of Perpetua's proposed mining plan of operations requires the Forest Service to consider whether to approve the proposed mining plan of operations or to require changes or additions necessary to meet the purpose of the regulations for locatable mineral operations.
Samuel Penney (Chairman)	19396	3	<p>The Tribe has committed thousands of hours and substantial resources evaluating the Project. In 2017, the Tribe reviewed Midas Gold's (now Perpetua Resources or "Perpetua") Plan of Restoration and Operations and submitted scoping comments on July 20, 2017. Based on this review and subsequent information, the Tribe, in October 2018, adopted a resolution opposing the Project. The Tribe concluded that the Project posed an existential threat to its treaty-reserved rights and resources, cultural resources, and other interests. On October 27, 2020, the Tribe submitted over 120 pages of substantive comments on the Draft Environmental Impact Statement ("DEIS").</p> <p>The Forest did not provide the Tribe with a comprehensive review of the Tribe's DEIS comments, only a cursory response that the Tribe received in anticipation of government-to-government consultation three days before the Forest's public release of the SD EIS. Since then, the Tribe has continued to closely monitor the Project through government-to-government consultation and staff-to-staff interactions with the Forest, emphasizing at every opportunity the Agency's obligations, as the Tribe's federal trustee, to protect the Tribe's treaty rights and resources.</p>	NEPA	Section 1.9 of the SDEIS states that the comments received on the 2020 DEIS were reviewed and considered as additional scoping input for the SDEIS preparation. These comments were analyzed in a content analysis process to develop public concern statements. Perpetua also reviewed the comments received on the 2020 DEIS and sought to respond to many of these comments by revising and resubmitting their Plan of Operations. This process produced the Modified Plan of Operations (ModPro2) submitted in October 2021, which then became the 2021 MMP which constituted a revised Proposed Action for Forest Service review. Sections 1 and 2 of the ModPro2 document explain how the changes in the modified plan of operations is partly in response to comments received on the 2020 DEIS. Appendix A of the ModPro2 document shows the comparison of the action alternatives reviewed in the 2020 DEIS and the ModPro2 plan. Because the 2021 MMP contained substantial changes to the Proposed Action that are relevant to environmental concerns the Forest Service decided to prepare a SDEIS. Also, based on comments received on the 2020 DEIS and the effects of the 2021 MMP, the Forest Service revised the action alternatives considered in the SDEIS. A major change in the format of the SDEIS and the 2020 DEIS was that technical supporting information was moved from the EIS to supporting specialist reports. The authors of these reports reviewed the public concern statements derived from the 2020 DEIS comments which advised the authors of the specialist reports regarding content of those reports to be responsive to what was learned from the 2020 DEIS reviews. Per 40 CFR § 1503.4(a) the Final EIS responds to individual comments or groups of comments. The Final EIS contains responses to the comments received on the SDEIS and concern statements summarizing comments on the DEIS.
Samuel Penney (Chairman)	19396	5	The Tribe is also concerned with the U.S. Department of Defense's ("DOD") recent decision giving Perpetua \$24.8 million, through a "critical minerals award," for the Project. According to the DOD, the money to Perpetua will be used to "complete environmental and engineering studies necessary to obtain a Final Environmental Impact Statement, a Final Record of Decision, and other ancillary permits." DOD's decision, which was made without any consultation with the Tribe regarding the effects of the Project on the Tribe's treaty-reserved rights, appears focused on facilitating authorization of the Project while the Forest's and Corps' review is underway and during the Tribal and public comment period. The Tribe expects that, under NEPA and other applicable federal law, any additional environmental or engineering review of the Project must undergo Tribal and public review through an additional SDEIS prior to a final decision.	NEPA	The Final EIS includes mention of the DoD grant which was announced after the SDEIS was released. The Forest Service understands the grant funds are for environmental and engineering work leading to a ROD. The Forest Service is not aware that this work will result in new information relevant to environmental concerns or bearing on the Proposed Action or its impacts to necessitate another SDEIS.
Samuel Penney (Chairman)	19396	18	National Environmental Policy Act Framework Section 101 of the National Environmental Policy Act ("NEPA") declares a broad national commitment to protecting and promoting environmental quality. The purposes of NEPA are: to declare a national policy which will encourage productive and enjoyable harmony between man and his environment; to promote efforts which will prevent or eliminate damage to the environment and biosphere and stimulate the health and welfare of man; to enrich the understanding of the ecological systems and natural resources important to the Nation; and to establish a Council on Environmental Quality. To ensure that NEPA's commitment is infused into the ongoing programs and actions of the Federal Government, the Act also establishes some important 'action-forcing procedures.' Section 102 directs, to the fullest extent possible, all agencies of the Federal Government shall: [I]nclude in every recommendation or report on proposals for legislation and other major Federal actions significantly affecting the quality of the human	NEPA	The specific concerns included in this comment are responded to in other comment/resources categories. No further response required here. General in nature or position statement.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Responses
			<p>environment, a detailed statement by the responsible official on--(i) the environmental impact of the proposed action, (ii) any adverse environmental effects which cannot be avoided should the proposal be implemented, (iii) alternatives to the proposed action, (iv) the relationship between local short-term uses of man's environment and the maintenance and enhancement of long-term productivity, and (v) any irreversible and irretrievable commitments of resources which would be involved in the proposed action should it be implemented. The statutory requirement that a federal agency contemplating a major action prepare an Environmental Impact Statement ("EIS") serves NEPA's "action-forcing" purpose in two important respects. It ensures that the agency, in reaching its decision, will have available, and will carefully consider, detailed information concerning significant environmental impacts; it also guarantees that the relevant information will be made available to the larger audience that may also play a role in both the decision-making process and the implementation of that decision. Simply by focusing the agency's attention on the environmental consequences of a proposed project, NEPA ensures that important effects will not be overlooked or underestimated only to be discovered after resources have been committed or the die otherwise cast.</p>		
Samuel Penney (Chairman)	19396	19	<p>1.0 FOREST SERVICE PURPOSE AND NEED FOR ACTION NEPA requires agencies to "briefly specify the underlying purpose and need to which the agency is responding in proposing the alternatives including the proposed action." In accordance with this requirement, the Forest Service articulated the purpose and need for the Project as follows:</p> <p>"The Forest Service's purpose is to consider approval of Perpetua's proposed use of the surface of [National Forest System] lands in connection with operations authorized by the U.S. mining law as first described in the Plan submitted September 2016, then refined in 2019 (Brown and Caldwell 2019a), and further modified in 2021 resulting in the 2021 MMP (Perpetua 2021a)." The Forest Service further articulated the "need for action" as to "[c]onsider approval of Perpetua's 2021 MMP for development of the SGP to mine gold, silver, and antimony deposits that, where feasible, would minimize adverse environmental impacts on NFS surface resources; and ensure that measures are included that provide for mitigation of environmental impacts and reclamation of the NFS surface disturbance."</p> <p>Failure to Consider Actual Purpose and Need for Project in SDEIS As articulated, the Forest Service's "purpose" and "need for action" in evaluating the Project sidestep the fundamental issue: is there a real world purpose or need for the Project? The SDEIS simply fails to address this basic question.</p> <p>The fact is there is not a clear purpose for the Project given its site-specific nature. There are other places in the world where gold, silver, and antimony may be mined with far less environmental impact than in the Project's proposed location. In addition, the SDEIS does not address whether there is current or future demand for gold, silver, and antimony in the United States or elsewhere.</p> <p>The United States is currently, and for the foreseeable future, a global supplier of gold and silver, and its current and future planned production of both metals exceeds global demand. Thus, there is no apparent need in the United States, including Idaho, for an additional gold or silver mine.</p> <p>More factual information is necessary to demonstrate the need to meet United States or global requirements for these minerals.</p> <p>Agencies have "discretion to develop and rely on statements of purpose and need that are consistent with the agency's decision-making responsibilities while considering multiple relevant factors, including the public interest and the goals of an applicant. Thus, the Forest Service should address whether there are other practicable alternatives that would meet the purported purpose and need for the Project that are protective of tribal treaty rights and are less environmentally damaging. The Forest Service should also include and analyze other alternatives, both nationally and globally for meeting gold, silver, and antimony demand and evaluate these alternatives in an SEIS. Such alternatives would include other proposed or developed projects or efforts throughout the world that would produce gold, silver, or antimony.</p> <p>Consideration of global purpose and need is particularly appropriate considering the natural and human resources that will be adversely affected if the proposed Project is permitted, constructed, and operated.</p>	NEPA	<p>The Forest Service's Purpose and Need meets the intent of the purpose and need as outlined in 40 CFR 1502.13 because the agency is responding to a plan of operations submitted by an external proponent. The Forest Service must comply with regulations governing the use of surface resources for operations authorized by the United States mining laws on National Forest System lands under 36 CFR 228, subpart A. These regulations require that the Forest Service respond to parties who submit a proposed plan of operations for approval to conduct operations authorized by the United States mining laws on National Forest System lands for part or all of their planned actions including mining, mineral processing, and uses reasonably incident thereto. In accordance with 36 CFR 228.5, the submittal of Perpetua's proposed mining plan of operations requires the Forest Service to consider whether to approve the proposed mining plan of operations or to require changes or additions necessary to meet the purpose of the regulations for locatable mineral operations. The Mineral Resources subsection of Section 4.2.2.2 of the SDEIS describes the markets for the products of the proposed operations and how these products would help meet the domestic and international demand for these products.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Responses
			<p>The EFSFSR has culturally-significant resources, and important fisheries and wildlife resources, all of which are critical to the Tribe and its treaty-reserved rights. The Tribe's way of life is intrinsically place-based, so adversely impacting or destroying a place also damages or destroys the cultural lifeways associated with it. Mining projects are an intense land use and are intrinsically destructive; therefore, the Project in the proposed location will cause substantial and irreparable multi-generational adverse impacts on the Tribe and its members that cannot be mitigated or restored. Avoidance of these impacts through careful consideration of the need for this Project is therefore essential.</p> <p>The Forest and Corps should address in the purpose and need section of the SDEIS the potential conflict between current and future uses of natural resources, including the harm the Project will do to the Tribe's treaty-reserved rights and resources and include mitigation measures.</p>		
Samuel Penney (Chairman)	19396	63	<p>SDEIS Section 2.4.6 Surface and Underground Exploration proposes that exploration and development drilling would occur to evaluate potential mineralized areas outside of the proposed mining areas. Five acres of new temporary road disturbance and eight acres of drill site disturbance on Forest lands at the mine site at any one-time during construction and operations. Exploration sites would be reclaimed after completion of drilling. Reclaimed acres would become available for future exploration, never exceeding 13 acres of disturbance at any one time. Disturbance resulting from surface exploration would total approximately 25 acres of roads and 40 acres of drill pads.</p> <p>The proposed exploration program to evaluate areas outside the proposed mining areas should be a separate proposal and include a detailed plan and environmental analysis of those actions on a stand-alone basis. The Golden Meadows Exploration Project EA serves as a starting point for the type of analysis that should be done for the additional exploration proposed in the SDEIS. The SDEIS should be supplemented to either remove this proposal or alternatively to provide additional details such as RCPs for the exploration areas.</p>	NEPA	It is not unusual to include within a mine plan of operations the reasonably foreseeable development and exploration work that would occur simultaneously with the mine construction and operations. The SDEIS and Final EIS include a resource-by-resource analysis of the effects of the development and exploration. If the future exploration or development drilling activities exceeded what is included in the mine plan of operations, the Forest Service would evaluate what additional NEPA analysis may be needed.

Elizabeth Barnes	6652	19	4-207 What measures are in place to prevent or mitigate the event of a mass failure of the TSF buttress and embankment wall?	MIN	The TSF embankment is designed to the regulatory standard required to minimize risk of a mass failure event. The TSF Buttress has been added downstream of the TSF Embankment to increase the dam performance beyond regulatory requirements. As such, the TSF Buttress is the design feature applied to mitigate mass failure risk.
Elizabeth Barnes	6652	29	4-230 Where is the pit backfill coming from and what is the composition and toxicity of this material?	MIN	SDEIS Table 3.9-2 describes the sourcing of pit backfill material and SDEIS Section 3.9.4.2 describes the geochemical characteristics of the rock material.
Elizabeth Barnes	6652	38	4-285 Where will material from the SODA and Bradley pits be relocated or remediated?	MIN	Section 2.4.5 describes how material from the SODA and the Bradley Mill would be re-processed or placed in the TSF embankment.
Conway Ivey (Executive Chairman, Ivy Minerals, Inc.)	13274	7	As for the larger project envisioned by the MMP, it is clear that both Perpetua and the USFS have put enormous thought and effort into identifying approaches to minimize the potential adverse environmental and human impacts. The USFS includes 117 separate items that must be instituted by the project based on existing regulatory and Forest Plan Requirements (Table 2.4-12). In addition, Perpetua has 155 individual Project Design Features (Table 2.4-13), which as the SDEIS notes, are uproject-specific measures intended by a proponent to inherently reduce and/or avoid potential environmental impacts of a proposed action. N In other words, design features and actions that will avoid, minimize or mitigate environmental impacts of the SGP. Collectively, the range of these requirements and commitments is vast, from fugitive dust capture (first of the two lists) to vegetation maintenance for safety (last). Reading through the list it seems first that anything and everything that could be thought of	MIN	Comment noted. Statement of position.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			to avoid, reduce or mitigate impacts of the project are somewhere in the list. And second, what project can anyone think of that has had such a vast "laundry list" of must dos, can dos, and will dos?		
Hendrickson, Emily (President, Women's Mining Coalition)	17429	19	<p>Table 2.4-13 of the SDEIS entitled "Proponent Proposed Design Features" lists the numerous voluntary measures called "Environmental Design Features (EDFs)" that Perpetua has committed to implementing to provide an extra level of environmental protection and stewardship. The EDFs go beyond the extensive federal and Idaho State regulatory requirements that are listed in Table 2.4-12. The voluntary EDFs are intended to further avoid impacts or minimize them as much as possible. As described in Section 2.4-9, "the EDF's may have the effect of reducing and/or eliminating potential environmental impacts of the SGP." Perpetua has committed to so many EDFs that Table 2.4-13 is 11 pages long.</p> <p>Perpetua's EDFs augment and enhance the comprehensive and effective Forest Service and state regulatory requirements, best management practices, and likely permit conditions listed in Table 2.4-12. These regulatory requirements plus Perpetua's voluntary EDFs, will ensure a high level of environmental protection at the SGP. It is clear from Tables 2.4-12 and 2.4-13 that the Forest Service, the Idaho State regulatory agencies, and Perpetua have worked constructively together to develop an environmentally sound project that will minimize adverse environmental impacts, achieve numerous environmental and socioeconomic benefits, and supply the U.S. with a critically important domestic source of antimony.</p>	MIN	Comment noted. Statement of position.
von Lindern, Ian (Founder, Terragraphics International Foundation)	17436	9	<p>The Preferred Alternative evaluated by the Forest Service relies on SGP assertions that Perpetua, or subsequent operators, will adhere to the 2021 MMP. Perpetua has a PTC to construct a facility capable of operating at 180,000 tons/day capacity and an amendable permit condition limiting production to 135,000 ton/day (75% of capacity). The Forest Service relies on Perpetua's assertion in the 2021 MMP that the SGP will operate at 29% of capacity. There are no provisions in the PTC permit conditions to limit SGP to the Forest Service assumed production level. IDEQ permit conditions allow production up to the 75% of capacity TRACT limit, and is amendable without federal oversight.</p> <p>The Forest Service only has Perpetua's unbound assurance that the SGP will operate according to the 2021 MMP. Table SD4 compares the Forest Service 2021 MMP, Maximum Design Capacity, and TRACT permitted emissions for Mining Fugitive Dust emissions. Table SD4 demonstrates the SGP is permitted by IDEQ to increase production, emissions and environmental releases by 2.5 times, and has the design capacity to increase emissions by 3 times. The Preferred Alternative is only constrained by amendable IDEQ Minor Source Permit conditions. Forest Service should consider the probability of SGP expansion, and evaluate potential impacts at the permitted and design capacity of the facility.</p> <p>Alarming, Perpetua's 2021 Technical Feasibility Study disclosure to Investors indicates that substantial additional resources are available for exploitation, including expansion of the current Pits, and several other on-property and nearby reserves. Other mining companies are actively exploring similar ore bodies nearby that could utilize the SGP mineral processing excess capacity. The SDEIS does not address these nearby reserves, or the lack of constraints on the SGP to exploit the excess capacity,</p>	MIN	The Forest Service decision on the Project extends only to the alternative selected as described by its plan. Modifications to that plan would require permit modification through additional NEPA analysis.
von Lindern, Ian (Founder, Terragraphics International Foundation)	17436	13	<p>Concurrent review of the serial Alternatives and support documents submitted to the Forest Service demonstrates that the Preferred Alternative is more than a refinement. As noted, it should be considered a new Alternative substituted for earlier DEIS Alternatives that were clearly insufficient.</p> <p>In comparing MoDPRO and MoDPRO2, mined material is decreased by 44 MT in the SDEIS Alternative. This is achieved by decreasing Development Rock (DR) by 61 MT and increasing Ore production by 17MT. This significantly changes the production, sources, concentrations, and toxicity of COCs from mining operations, and the disposition of COCs downstream in metallurgical processes and environmental media (Tables SD1b and SD1c).</p> <p>Most of the gold at SGP is refractory, i.e., chemically bound as small particles in arseno-pyrites. Massive amounts of these ores and Development Rock (DR) are mined to access this gold. The SDEIS Preferred Alternative mines nearly 400 million tons of material. Approximately 290 – 866 pounds of arsenic, 0.2 -</p>	MIN	The SDEIS analyzed the 2021 MMP as proposed by Perpetua to assess its environmental effects and to determine mitigation requirements. Geological, air quality, and water quality effects are described in Sections 4.2.2.2, 4.3.2.2, and 4.9.2.2, respectively.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>0.63 pounds of mercury, and 71 - 304 pounds of antimony will be disturbed for each ounce of gold produced (average - 95th%tile) (Table SD2).</p> <p>Overall, arsenic, mercury, and antimony mined are reduced by 15%, 25% and 40%, respectively, from totals estimated in the DEIS. The decreases are due to reduced DR from Hangar Flats Pit (HFP) offset by decreases in the DR/Ore strip ratio, and increasing Ore production in the West End Pit (WEP). About 17MT, or 18%, more Ore will be produced in the SDEIS Alternative than in the DEIS.</p> <p>COCs in ores decrease by 5% overall, with 20% and 224% increases in Yellow Pine Pit (YPP) and WEP Ore arsenic, respectively, and a 75% decrease in HFP Ore arsenic (Table SD1c).</p> <p>Estimated gold recovery increased by 5% from 4040 - 4238 koz. Antimony product increased from 16% from 98.9M to 115M pounds, despite the 40% decrease in antimony ore production. This accomplished by a 32% increase in recovered YPP antimony offsetting a 31% decrease in antimony recovered from HFP. Antimony ores will be mined in years 1-6, and 64% of product will be recovered in years 1-4. There is no appreciable antimony ore in the WEP, and no antimony ores will be produced after Year 7. Table SD2 shows gold production and Table SD5 shows antimony production for the DEIS and SDEIS.</p> <p>The purported remediation of historic wastes and tailings represents about 3% of total disturbed arsenic and 5% of disturbed mercury and antimony on site. All of the remediated arsenic, and >75% of remediated mercury and antimony will be redistributed on site. Undetermined percentages of mercury will leave the site as high-level waste, be disposed in DR or discharged to the TSF. About 22% of remediated antimony and 47% of ore antimony will be recovered as antimony concentrate for off-site sale. The remainder will be disposed on-site.</p> <p>Approximately 36% of disturbed antimony will be recovered and 64% wasted. About 16% of disturbed antimony will be disposed of in DR repositories in about equal amounts above and below ground. About 47% of disturbed antimony will be discharged to the TSF, largely as flotation tailings.</p> <p>Table SD3 shows SDEIS COC production and disposal.</p> <p>Regarding arsenic, an estimated 616,000 - 1,856,000 tons (average - 95th%tile) of arsenic is mined in the SDEIS configuration. Approximately 36% of site-wide arsenic (102,560 - 827,600 tons) is in Development Rock (DR) and historic overburden, and 64% (309,580 - 1,028,400 tons) in ore. Practically all of this arsenic will be disposed of on-site or released to the immediate environment. Three principal concerns are arsenic in air from mining dust, DR disposed in locations subject to groundwater and meteoric waters, and in ores disposed in the Tailings Storage Facility (TSF) after gold extraction. Over time, all three sources will release arsenic to the local environment (Table SD3).</p> <p>The SDEIS Preferred Alternative effected large changes at the WEP, the fugitive dust source most affecting the compliance point for arsenic exposures. COC production in WEP Ores increases by more than 3.2 times, and WEP DR COCs increase 14%. The WEP is expected to yield 175,320 - 597,200 tons of arsenic (average - 95th %tile), nearly doubling (1.97X) the estimate for the DEIS. The change in strip ratio increases weighted arsenic concentrations for mined material in the WEP by 1.5 times, from 569 - 2079 ppm to 887 - 3021ppm (average -95th%tile). Weighted concentrations remain similar to the DEIS, at 2240 - 6350 ppm in the YPP and 3436 - 10,170 ppm in the HFP (Tables SD1a, SD1b and SD6).</p>		
von Lindern, Ian (Founder, Terragraphics International Foundation)	17436	27	<p>The Arsenic Stability Investigation (2020) was the genesis of the HAC assurances provided in the SDEIS. The 2021 Feasibility Study, MoDPRO2 and SDEIS documents confuse the HAC acronym, with the Feasibility Study distinguishing Hot Acid Cure (HAC) and Hot Arsenic Cure as (HC), in contrast to the MoDPRO2 and SDEIS documents using only Hot Arsenic Cure (HAC). Regardless of the confusion, it is most important to note that the supposed process indicated in the MoDPRO2 refinements, and the four SDEIS sentences, are based on 3 tests of a single concentrate, representing “years 1-4 production consisting of 85% Yellow Pine and 15% Hangar Flats (Con 10).” The 2021 Feasibility Study also indicates the HAC system would be installed in Year 6 to be operational in Year 7, when arsenic levels in the mill feed are expected to increase. This corresponds with the completion of YPP and HFP ores and the introduction of WEP ores for which there were no reported HAC tests. This indicates the HAC will</p>	MIN	<p>The SDEIS applies the acronym for hot arsenic cure consistently with its use in the proposed mine plan description.</p> <p>As stated in the Project description, the hot arsenic cure treatment would be applied if soluble arsenic levels were higher than anticipated. Further, processing residuals containing arsenic would be placed in lined facilities that inhibit exposure of those materials to the environment.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>not be installed in time to treat the majority of concentrates that were tested, and was never tested on the concentrates it is intended to treat.</p> <p>It is also important to note that the amorphous arsenic concern is with the final discharge in a six step detoxification flowchart. This occurs after the supposed HAC stabilization of thermally treated arsenic in the POX in an earlier step. The supposed stabilized CN/Detox slurry was then blended with concentrator tailings thickener underflow, and the blend was examined for arsenic stability. The blend ratio was 75.2% rougher tailings, 12.0% cleaner tailings, and 12.8% cyanide detox residue. As a result, it is unclear if the alleged stabilization in the final discharge is due to dilution from rougher and cleaner tailings, or from the alleged effectiveness of the HAC.</p> <p>Considering the complex arsenical geochemical differences in ores processed, and the shift in the 2021 MMP toward WEP Ores (that demonstrated significantly different arsenic recovery chemistry due to unique combinations of sulfide, oxidized and transitional ores), the Forest Service should have little confidence in Perpetua's ability to manage arsenic stability through the Life of the Mine (LOM).</p>		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	35	<p>I. Failure to include necessary information on the tailings dam</p> <p>Another serious flaw in the technical analysis is the failure to include technical reference documents containing technical specifications and analysis of the tailings dam. The SDEIS refers to calculated factors of safety for both static and seismic considerations, and provides the updated seismic risk analysis necessary to make these calculations, but is still lacking the basic engineering specifications for the dam itself. For example, there is no discussion of the specifications for the fill for the different sections of the dam, and how the quality assurance for dam construction will be performed. Developing this information is standard procedure for an EIS, and since the fundamental dam design does not appear to have changed since at least 2017, there should have been more than sufficient time to develop this information.</p>	MIN	The IDWR is the proper authority in Idaho to regulate design, construction and operation of dams, including tailings disposal facilities. These requirements are cited in Section 3.2.3 of the EIS. Perpetua would need to comply with the IDWR regulations and requirements for its TSF. The monitoring requirements for the TSF would be established by the IDWR permitting process and the Forest Service recognizes the primacy of the IDWR in these matters, so has therefore not specified monitoring of the TSF in the EIS.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	36	<p>J. Insufficient information about the autoclave</p> <p>The autoclave is a major component of the ore processing system. It operates at very high temperatures, and requires pure oxygen as a continual input. Any mercury in the ore processed in the autoclave will be volatilized into the autoclave exhaust, along with other potential contaminants, like arsenic. There is no detailed discussion of this system, its emission controls, or how its fuel and oxygen needs will be met. Because the mercury emission control systems must operate at a very high efficiency in order to conform to air quality requirements, monitoring their performance is very important. There is no discussion of the efficiency at which these control systems must operate, or how and when the mercury emission control systems will be monitored. Autoclave operation needs to be given more importance in the SDEIS, and a thorough discussion of the monitoring for air emissions from the autoclave, for mercury and any other potential contaminants, needs to be provided.</p>	MIN	The IDEQ is the proper authority in Idaho to regulate design, construction and operation of ore processing facilities and their environmental controls. These requirements are cited in Section 3.3.3 of the EIS. Perpetua would need to comply with the IDEQ regulations and requirements for its TSF. The monitoring requirements for the autoclave system would be established by the IDEQ permitting process and the Forest Service recognizes the primacy of the IDEQ in these matters, so has therefore not specified monitoring of the autoclave system in the EIS.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	37	<p>K. Additional information needed about underground exploration</p> <p>A mile-long exploration tunnel is being authorized as part of the SDEIS. Underground exploration could potentially impact water quality and quantity. Drilling this exploration tunnel involves the surface disposal of rock with undefined geochemical properties, which could affect the type and level of contaminants that leach from this rock. The only information provided about this project is limited to 10 sentences. The lack of information, data, and analysis in the SDEIS is blatantly insufficient to authorize an activity of this scope.</p> <p>In addition to the development rock sources included in Table 3.9-2, advancement of the Scout Exploration Decline is expected to produce 25,000 tons of development rock, approximately 0.01 percent of the project's total mined material. The development rock from the Scout Exploration Decline would consist of the metasedimentary lithologies of the Stibnite roof pendant most prevalent in the West End area including quartzite, carbonate and schists with diorite and quartz monzonite intrusives (SRK 2021a). The development rock from the decline would be destined for the buttress and backfill locations along with the West End pit development rock. Hence, the characterizations of the open pit mined</p>	MIN	<p>SDEIS Section 3.9.4.2 describes the geochemical characteristics of proposed mined materials. These characteristics are associable with lithology as determined from testing drill hole samples.</p> <p>Because the Scout Decline was included in the proposed mine plan, it was analyzed in the EIS. Activity beyond the currently proposed decline installation and exploration drilling would require additional permitting through NEPA.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>lithologies (Table 3.9-3) are applied to the limited amount of those lithologies present in the development rock from the Scout Exploration Decline. SDEIS 3-151. (Emphasis added.)</p> <p>Inferring characteristics from other locations and limited drill samples of the underground area is not sufficient analysis to permit underground mining. Stand alone exploration tunnels such as this have warranted their own NEPA analyses, including the decline for exploration for the Idaho Cobalt Project as well as the EIS for underground development of the Idaho Cobalt Project in which the Forest Service disclosed the geochemical properties of the underground material, discussed how this material was going to be segregated, handled, stored or backfilled, and included extensive information on water quality monitoring and water treatment related to underground mining.</p> <p>In 1994, the Boise National Forest permitted underground exploration of the Talache Level 900 adit through a Categorical Exclusion without taking a hard look at water treatment needs. The Forest Service did not require a bond for water treatment and has been entirely reliant on the absentee operator to deal with this discharge. Under a court ordered settlement, the operator obtained an NPDES permit for this discharge in 2009 but has been unable to effectively treat this water since, leading to frequent arsenic and iron discharge concentration violations. The operator was subsequently penalized \$2 million dollars for Clean Water Act violations and ordered to come into compliance. More recently, since the spring of 2020, arsenic concentrations within discharge from the 900 adit have significantly increased exceeding modern permitted arsenic standards by as much as 12,000%. Despite court order and recent letters from the Boise National Forest to the mining company, the site continues to violate the Clean Water Act to this day. The Payette National Forest needs to fully address all aspects of the underground exploration for the SGP.</p>		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	81	<p>2. Management plans for waste are poorly developed or completely undeveloped.</p> <p>Management plans for waste rock and tailings are poorly developed or completely undeveloped and will need more supporting information and detail in the Final SEIS. According to the Development Rock Management Plan (DRMP), active segregation of PAG/metal leaching material is not required, presumably because this material will be placed in the pit as backfill or in the TSF buttress. Such an assumption relies on the performance of engineered measures to limit the transport of mine-influenced leachate from the pits and the TSF buttress to downgradient water bodies. Cutoff values for rock with low ARD/ML potential (which could be used for facility construction materials) are defined in the DRMP as ≤ 500 mg/kg total arsenic and NPR values >1.5. However, a substantial number of HCT samples with NPR values >1.5 had elevated arsenic release rates, and samples with total arsenic values <500 mg/kg leached arsenic in excess of the federal drinking water standard of 10 mg/L. The adaptive management plan (AMP) or plans are not developed. These and other management plans should be developed and available for public review in a revised SDEIS.</p>	MIN	<p>The segregation of mined material for use is associated with the implementation of Project design features that control leaching and runoff from development rock. Project approval would require implementation of both measures.</p> <p>Few existing waters on site have arsenic concentrations below the federal drinking water standard. The cutoff values are applied to segregate materials with arsenic leaching potential beyond existing conditions.</p>
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	123	<p>E. Perpetual water treatment</p> <p>The assumption for the SDEIS appears to be that there will be no seepage, or de minimis seepage, from the tailings after initial seepage drain down. Until an actual post-closure seepage rate can be established, for both tailings drain down and buttress seepage, it is not reasonable to assume seepage from the waste rock in the buttress will be low enough so that long-term water treatment will not be required. Given the uncertainties in the water quality modeling, the SDEIS should assume that perpetual water treatment will be required, and calculate financial assurance to cover long-term water treatment costs, until post-closure monitoring proves otherwise.</p>	MIN	Comment noted. Statement of position.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	124	<p>1. The lack of technical information and supporting data on the design of the proposed construction approach of the tailings dam precludes review of its adequacy (citing David Chambers technical report)</p> <p>The design, construction, operation, and closure of a tailings facility, primarily the tailings dam itself, is the most important mine-related structure to be analyzed in an EIS because of the potential environmental, economic, and public safety liabilities associated with a structure that must function properly for millennia"... "Normally the references for an EIS would include a technical report from an engineering company experienced in the design, construction, operation, and closure of tailings dams.</p>	MIN	The IDWR is the proper authority in Idaho to regulate design, construction and operation of dams, including tailings disposal facilities. These requirements are cited in Section 3.2.3 of the EIS. Perpetua would need to comply with the IDWR regulations and requirements for its TSF. The monitoring requirements for the TSF would be established by the IDWR permitting process and the Forest Service recognizes the primacy of the IDWR in these matters, so has therefore not specified monitoring of the TSF in the EIS.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>The SDEIS references do not include such a report. The SDEIS refers to the Feasibility Study (M3 2021) for many of its technically related comments on the tailings storage facility, but the feasibility study itself does not contain technical information on the tailings dam. The figures presented in the SDEIS, Figures 2.4-10 and 2.4-11, suggest that at least some preliminary engineering work has been performed, but there is no reference given for the source of these figures, which by themselves are wholly inadequate to permit the construction of a tailings dam.</p> <p>Technical information and supporting data on the design and construction of the tailings dam are particularly important for review in the SDEIS because recent research examining all serious tailing failures since 1915 demonstrates that the rate of serious and very serious tailings dam failures has increased globally:</p> <p>[T]he 100 years of TSF failures shows an emerging and pronounced trend since 1960 toward a higher incidence of "Serious" and "Very Serious" failures. That is, the consequence of loss is becoming increasingly greater. 49% (33/67) of all recorded Serious and Very Serious failures from 1940-2010 have occurred since 1990. Of all 52 recorded incidents cited, 1990-2010, 17 (33%) were Serious failures, i.e. large enough to cause significant impacts or involved loss of life. Another 16 (31%), were Very Serious failures, i.e. catastrophic dam failures that released more than 1 million cubic meters of tailings and in some instances resulted in multiple loss of life. 63% of all incidents and failures since 1990 were Serious or Very Serious. The total costs for just 7 of these 16 large failures was \$3.8 billion, at an average cost of \$543 million per failure. These losses, according to dam committee reports and government accounts, are almost all the result of failure to follow accepted practice. 168</p>		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	127	<p>4. Autoclave details are lacking</p> <p>As noted in Chambers (2022), the Forest Service needs to describe autoclave operation in more detail than it presently receives in the SDEIS, and a thorough discussion of the monitoring for air emissions from the autoclave, mercury and any other potential contaminants, needs to be provided. Mercury emission control systems must operate at a very high efficiency in order to conform to air quality requirements but there is no discussion of the efficiency at which these control systems must operate, or how and when they will be monitored.</p>	MIN	<p>Section 2.4.5.7 summarizes the autoclave system operations. Additional details can be located in the cited references regarding the Project design.</p> <p>SDEIS Section 4.3.2 describes the air emissions associated with the Project including the autoclave system and the predicted effects of those emissions on air quality and mercury deposition. The autoclave system emissions are subject to regulation by IDEQ under their air quality permit to construct.</p>
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	136	<p>9. The SDEIS should provide a detailed plan for temporary closure</p> <p>The SDEIS states that the Cyanidation Facility Permanent Closure Plan will provide details on how water will be managed during a temporary closure (RCP, p. 5-1), but that plan is not provided in the SDEIS. Without that plan, the SDEIS fails to provide adequate information to demonstrate that plans and mitigation measures are in place to prevent significant harm during a period of temporary closure.</p>	MIN	<p>The requirements for temporary closure or emergency shutdown are described in the Reclamation Closure Plan and the Water Management Plan and are summarized in the EIS. The incorporation of a plan fulfilling those requirements would be required as part of the Project decision.</p>
Idaho Regulatory Agencies	17718	153	<p>Current text: "Any contact water beneficially used in the ore processing or for dust control or stored for more than 24 hours then treated and discharged would require water rights permitting through the IDWR prior to use." For clarification, add: "...would require water rights permitting, including mitigation as outlined in the water right permit, through the IDWR prior to use"</p>	MIN	<p>Revision made per comment.</p>
Idaho Regulatory Agencies	17718	23	<p>"An autoclave system would be used to oxidize the sulfide minerals comprising the gold and silver concentrate to liberate the gold and silver for subsequent leaching." This is not correct, due to misuse of terms. Suggest: <i>An autoclave pressure-oxidation system would be used to oxidize the gold- and silver-bearing sulfide minerals. Once oxidized, the gold and silver can then be liberated from the sulfide minerals by subsequent cyanide leaching.</i></p>	MIN	<p>Revision made per comment.</p>
Idaho Regulatory Agencies	17718	24	<p>"operated consistent with the International Cyanide Management Code for the Manufacture, Transport, and" Question: Is Perpetua a signatory of the Cyanide Management Code or will they be operating consistently with it?</p>	MIN	<p>Perpetua or any other future operator would be operating consistently with the International Cyanide Management Code.</p>
Idaho Regulatory Agencies	17718	26	<p>Is this a carbon-in-pulp circuit as described above and shown on process diagrams? Where is the CIL circuit?</p>	MIN	<p>The mention of CIL has been replaced with CIP.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Idaho Regulatory Agencies	17718	27	What is the large white area in the figure? It's a cutaway projection drawn parallel to the proposed fish passage tunnel. Please provide a label or explanation on the figure or within the caption.	MIN	The white area has been identified in the figure legend.
Idaho Regulatory Agencies	17718	28	(3) Contact water..... and roads therein. Please note that all water will need to be tested before use.	MIN	Contact water collected within open pits may be used for dust control on roads with the pits. Dust control on roads outside the active mining area would be derived from water supply wells or non-contact water collected.
Idaho Regulatory Agencies	17718	29	The project's water treatment requirements, objectives and methods are described in detail in the Stibnite Gold Project Water Management Plan (Brown and Caldwell 2021b) and summarized in this section. Three water types would require treatment over the life of the SGP: contact water from mine facilities, which includes dewatering water (construction through closure); process water from the TSF (closure); and sanitary wastewater (construction through early closure). Please note that all water must be tested before use.	MIN	Contact water would be used for process make up water or dust control within active mining areas. Water use and dust control outside of the active mining areas would be derived from non-contact sources. Water testing requirements for produced and treated waters would be proscribed by the operating permits issued by IDEQ with additional environmental monitoring requirements for surface water and groundwater included in the Water Resources Monitoring Plan which would be required by the ROD.
Idaho Regulatory Agencies	17718	30	paragraph 1, line 4: During construction and early in operations, a modular, mobile, <u>two-stage iron coprecipitation system</u> would be utilized. But then, paragraph 2 line 1: This is met with a staged water treatment strategy. The construction time period is paired with 300 gpm of peak capacity from <u>package iron coprecipitation plants</u> . Comment: This is confusing. Is <u>system</u> and <u>plant</u> the same thing? If so, please use only one name. If not, please explain.	MIN	The term "plant" has been replaced with "system" for consistency.
Idaho Regulatory Agencies	17718	31	States: At closure, the closure water treatment plant would be constructed to accommodate treatment of water from the TSF which would include iron coprecipitation and the application of reverse osmosis membrane treatment. Comment: It was understood the existing water treatment plant in Meadow Creek would be moved to the TSF. This statement says a new plant will be constructed. Also, use of the term "closure" is being used for different meanings in different places of the document. Terms should be used consistently throughout.	MIN	The text has been revised to clarify that a new water treatment plant would be constructed at a new location prior to the closure period.
Idaho Regulatory Agencies	17718	32	Native earth materials would be required for some applications. Specific areas within the SGP that have large quantities of high quality native alluvial and glacial granular borrow materials for use include: • The alluvial and glacial soils in the Meadow Creek valley floor within the footprint of the TSF, TSF Buttress, Hangar Flats pit, and Yellow Pine pit; • Sand, gravel, and cobbles in the lower Blowout Creek alluvial fan; and • Glacial soils in the Fiddle Creek valley walls within the footprint of the Fiddle GMS. Comment: "Large quantities of high quality native alluvial and glacial materials" is a relative term. This statement is a bit misleading. There may be some areas with high-quality material; however, it will be used in the most critical areas for the hopes of re-vegetation success. It doesn't say anything about the poor to fair quality of GM material as noted on pages 11 and 12 of the Executive Summary. It also doesn't mention the deficit on GM material	MIN	The statement describes the plan to collect seed bank materials or high-quality materials for Project use. General soil conditions are described in Section 3.5 and limitations on the availability and quality of growth material are described in Section 4.5.2.2.
Idaho Regulatory Agencies	17718	33	1. The State of Idaho defines Reclamation as the process of restoring an area affected by a mining operation or cyanidation facility to its original or another beneficial use, considering previous uses, possible future uses, and surrounding topography. The objective is to re-establish a diverse, self-perpetuating plant community, and to minimize erosion, remove hazards, and maintain water quality (IDAPA 20.03.02.010.20). 2. The State of Idaho defines Closure as the decommissioning and reclamation of the cyanidation facilities and all materials treated with cyanide (IDAPA20.03.02.071, .080, .091, .111, .112, .120., .140., and .150). Please see additions in Glossary. It appears that as written, closure and reclamation are used interchangeably. 3. The general concept of concurrent reclamation is to reclaim areas no longer needed for continued mine operations. Please consider how to clarify. For each of the following primary areas that would undergo concurrent reclamation or simply reclamation, the topic sentence to each discussed feature should state when reclamation will occur. Also, please note that the referenced Reclamation and Closure Plan (Tetra Tech, 2021a) has not been submitted to IDL for	MIN	A definition of concurrent reclamation has been added to Section 2.4.7.1 to clarify its use in the description.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			review as part of the mine plan reclamation application, and may not meet all requirements of IDAPA 20.03.02		
Idaho Regulatory Agencies	17718	35	"ASAOC activities as described under the No Action Alternative would occur concurrent with 2021 MMP activities." This sentence placement and usage is confusing. Please spell out ASAOC, then explain why this is being discussed here, and then how can ASAOC activities occur concurrent with 2021 MMP activities? Haven't ASAOC activities already started? The 2021 Modified Plan activities have not started. Please note that MMP is not defined in Abbreviations.	MIN	The sentence has been removed and acronym use has been checked.
Idaho Regulatory Agencies	17718	36	As written: "minimum of 2 feet of a combination of 1.5 feet of backfill and 0.5 feet growth media..." Which means that it is a mixture of 1.5 feet and 0.5 feet. Is this what is meant? Or are you wanting to state that, a minimum of 1.5 feet of backfill (consisting of what?) and then 0.5 feet of growth medium on top of the placed backfill? But Tetra Tech, 2021a details the thicknesses of Growth Medium and Seed Bank Material to be used at the various sites. These are not consistent. Please make consistent and clarify.	MIN	The text has been revised to clarify that the minimum 2 feet consists of a minimum 1.5 feet of backfill and minimum 0.5 feet of growth media.
Idaho Regulatory Agencies	17718	37	First sentence: Perpetua would decommission and close underground facilities and underground support facilities, <u>including</u> the portals of the East Fork SFSR tunnel and Scout decline. Comment: "including" means there are others? Please clarify. While this section is about "decommission and close" of the Scout decline and fishway tunnel -- where will the mined material from the fishway tunnel be placed during construction? Is it processed or is it stockpiled? IDL has a call into Perpetua for this answer (12/30/2022). Please note: If the material is processed through the mill, then the fishway tunnel will need to be permitted under IDAPA 20.03.02.070.	MIN	The two portals mentioned represent the underground facilities. In addition, there would be support facilities located near the portals that would also be closed. Mined material from the tunnel would be commingled with development rock from the Yellow Pine Pit and managed per the Development Rock Management Plan, i.e., utilized as construction material or placed in the TSF Embankment/Buttress.
Idaho Regulatory Agencies	17718	38	A sinuous channel would be constructed through the backfilled area for the reconstructed East Fork SFSR with an average valley gradient approximating the historical, pre-disturbance river gradient (Tetra Tech 2021b). Note: reference could not be located on Payette National Forest website. Also please state what the gradient is here.	MIN	Comment noted. The precise historical gradient is not known because it was removed by the pit excavation. The typical gradient in that area is approximately 4%.
Idaho Regulatory Agencies	17718	39	Need a topic sentence. When would reclamation begin and end? Would this be concurrent reclamation, or final reclamation? Here's a potential example to help answer: <i>Concurrent Reclamation of the Yellow Pine Pit would occur during Mine Years X and Y. Concurrent Reclamation would consist of completely (?) backfilling the pit using the following material and their percentages of the total fill: West End pit Development Rock (90%); Hangars Flat pit Development Rock (5 percent); and Yellow Pine pit Development Rock (5 percent).</i> But not all of the pit is reclaimed, correct? What portions of the highwalls would remain above backfill? AND - are you stating that the highwalls would not be reclaimed? But, benches should be reclaimed by ripping and placing Growth Medium, then seeded. Please include that, after the Yellow Pine pit is partially backfilled to, at minimum, the valley floor level, it will still have highwalls ~500 to ~ 600 feet high.	MIN	The text has been revised to clarify that highwalls would be present above the backfill.
Idaho Regulatory Agencies	17718	40	Need a topic sentence. See comment for Yellow Pine Pit. As written, the West End Pit would not be reclaimed. That should be included in the topic sentence. Here's an example: <i>The West End pit area includes the West End pit, the Midnight pit, the sidehill pit, and the Development Rock from legacy mining activity. Reclamation would occur (when?). The West End pit would not be reclaimed. Instead, a pit lake about 400 feet deep would be allowed to form in the main portion (what is the main portion? 80% of the pit outline to valley level?) by routing West End Creek into the pit via a rock-filled chute on the west or east or north or south (?) highwall. The highwall, which would be about 900 feet above the pit lake surface.</i> Then, discuss detail, plus what reclamation would occur on the highwall = on the benches.	MIN	The text has been revised to clarify that the West End pit would not be reclaimed but would become a pit lake post-closure.
Idaho Regulatory Agencies	17718	41	This paragraph states that there is modeling uncertainty regarding the West End Pit Lake fill rate. "If water levels approach the threshold, either or both surface water diversion and water treatment could be implemented to prevent the lake from spilling. If needed, a temporary treatment unit would be mobilized to the site to treat and discharge the pit lake water until the lake level falls below the threshold discharge level, thus preventing untreated discharge in potential subsequent wet weather years and enabling gradual and predictable water treatment rather than treatment at higher but variable and uncertain peak	MIN	Sections 4.8.2.4 and 4.9.2.4 describe uncertainty regarding water quantity model predictions and Sections 4.8.3 and 4.9.3 describe mitigation measures to address model uncertainty. At present, overflow from the West End pit lake is not anticipated. If data collection and model updates do not resolve this prediction uncertainty or if overflow is subsequently predicted, the Reclamation Closure Plan would be modified to incorporate monitoring and management of pit lake outflow prior to Project closure.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			spring runoff rates". Comment: How will this potential problem be monitored? Where would the pit lake diversion water be discharged, either untreated or treated? Where would this temporary treatment unit reside prior to mobilization? How long would it take to mobilize the equipment? What kind of treatment unit is this?		
Idaho Regulatory Agencies	17718	42	Topic sentence states that reclamation will be completed 9 years after mining. When would reclamation begin? Example topic sentences: <i>Concurrent Reclamation on portions of the Tailings Storage Facility (TSF) would begin 3 to 5 years after end of tailings deposition. Additional Reclamation would begin on the Tailings Storage Facility (TSF), its Buttress, and the water treatment plant about 9 years.....</i>	MIN	The text has been revised to clarify reclamation timing.
Idaho Regulatory Agencies	17718	43	These time frames should be stated as crude estimates, especially for consolidation of tailings "beginning within 3-5 years from the end of deposition." As written, it will be 3-5 years. This is highly optimistic.	MIN	The text has been revised to indicate that timeframes are predicted timeframes.
Idaho Regulatory Agencies	17718	44	Topic sentence needed. When does reclamation begin? What all would be reclaimed? What features are not reclaimed? Please include that the Hangar Flats pit will have a highwall about 700 feet high. The highwall itself will not be reclaimed; however, the benches will be ripped as needed, covered with adequate Growth Medium, seeded, etc.	MIN	The text has been revised to clarify reclamation timing and that highwalls would be present above the backfill.
Idaho Regulatory Agencies	17718	45	This section is out of place. It is important, and relates to all of the reclamation because Perpetua's estimates predict a deficit of 800,000 CY. Each of the previous subheadings all use Growth Medium. Therefore, consider moving up, maybe to end of 2.4.7.1 - Overview? First sentence: need topic sentence for this section. Then, discuss and summarize what is presented in Tetra Tech, 2021a. Please note that this is NOT how Tetra Tech, 2021a represents the data. They contend that their proposed thickness are <u>consistent</u> with the thicknesses of Growth Medium <u>prescribed</u> at mines in Montana. Then, another paragraph is needed to summarize the Growth Medium deficit.	MIN	Sections 3.5 and 4.5.2.2 provide a more detailed description of the proposed reclamation, criteria, and monitoring.
Idaho Regulatory Agencies	17718	46	"Except for the Hangar Flats pit highwall above the valley bottom, the West End pit, and a portion of the Yellow Pine pit highwall, Perpetua would contour and grade disturbed areas to blend into the surrounding topography and terrain. Compacted areas such as roads, ore stockpile areas, parking lots, fuel storage areas, and building sites would be prepared prior to placement of growth media and revegetation. Haul routes and access roads would be re-contoured to establish natural drainage patterns." However, this is in contrast to what is stated on page 4-78 of this report: "The 2021 MMP consists of a 3-year construction period, approximately 12-year production period, 5-year closure period, and 5-year plus post-closure period. All the SGP-related disturbance at the mine site would be subject to reclamation activities, with the exception of approximately 278 acres associated with the Hangar Flats high walls, the West End pit lake and high walls, Yellow Pine pit high walls, the Stibnite Lake feature, plus the Midnight, West End, and Plant Site ponds. These areas would remain a permanent commitment of soil resources (a large portion of which would occur on private patented mining claims). For all other areas in the activity area, disturbance would be subject to the reclamation activities detailed in the Reclamation and Closure Plan (Tetra Tech 2019a, 2021a)." And please note that just because this occurs on private land does not mean that this is somehow acceptable. Disturbance on private land is under the purview of the Idaho Department of Lands, and anything not reclaimed would have to be agreed to before mining can begin.	MIN	The text has been revised per the comment with the Stibnite Lake Feature and the three ponds noted in Section 2.4.7.12. "Except for the Hangar Flats pit highwall above the valley bottom, the West End pit, a portion of the Yellow Pine pit highwall, the Stibnite Lake feature, and the Midnight, West End, and Plant site ponds. Perpetua would ..." As indicated in the comment, reclamation plans are subject to approval by IDL.
Idaho Regulatory Agencies	17718	47	"Post Closure Water Treatment." Closure refers specifically to the decommissioning and reclamation of the cyanidation facilities and all materials treated with cyanide (IDAPA20.03.02.071, .080, .091, .111, .112, .120., .140., and .150). Then, the topic sentence of the first paragraph states that treatment is during closure and reclamation..... Please consider a new heading that reflects what this section covers: <i>Tailings Storage Facility and West End Pit Water Treatment</i>	MIN	The section header is appropriate with the descriptions of the TSF and West End pit water management stated in the section text.
Idaho Regulatory Agencies	17718	48	Corrections needed as follows. <i>Evaluation of water treatment for the Tailings Storage Facility (TSF) is ongoing, and will be documented in the Closure of Cyanidation Facilities and Reclamation Plan. Water sources that will require treatment during Closure and Reclamation include the TSF Facility runoff, TSF consolidation water, TSF Buttress toe seepage, and, potentially, West End pit lake water.</i> [Buttress is capitalized, so it is assumed this means it is formal and has been defined in the Glossary. Buttress is	MIN	Sections 4.8.2.4 and 4.9.2.4 describe uncertainty regarding water quantity model predictions and Sections 4.8.3 and 4.9.3 describe mitigation measures to address model uncertainty. At present, overflow from the West End pit lake is not anticipated. If data collection and model updates do not resolve this prediction uncertainty or if overflow is subsequently predicted, the

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			missing. Suggested definition is included in Glossary]. Paragraph 3: How will West End pit lake be accessed by personnel, and who will continue to monitor water levels and for how long? Into perpetuity?		Reclamation Closure Plan would be modified to incorporate monitoring and management of pit lake outflow prior to Project closure.
Idaho Regulatory Agencies	17718	49	This needs clarification. AADT is only used once. Please spell it out. Here's a suggested rewrite: <i>Most Closure and Reclamation traffic would occur during May through November, as weather permits. Annual average daily traffic counts are estimated at 27 total vehicles (15 heavy vehicles and 12 light vehicles).</i> Is there definitions somewhere that differentiates heavy from light? If so, please include here, or in Glossary.	MIN	The acronym AADT is used 11 times throughout SDEIS Chapter 2 and is spelled out after its initial used. Definitions of heavy vehicle and light vehicle have been added to the glossary in Chapter 7.
Idaho Regulatory Agencies	17718	50	Entire section needs work. It needs an intro paragraph on monitoring, or is it monitoring and mitigation?	MIN	The section refers to monitoring as described in the section text, no revisions made.
Idaho Regulatory Agencies	17718	51	Edit first and second sentences for clarity and spell out EMMP, as this is not a common initialism.	MIN	Revision not accepted. Text is appropriate as written. EMMP was spelled out previously in the Chapter.
Idaho Regulatory Agencies	17718	52	The topic sentence conflicts with Table 2.4-12.	MIN	Text revised to "The SGP must comply with all laws and regulations that apply to the proposed activities with the most prominent requirements relating to the affects analysis appearing in Chapter 4 summarized in Table 2.4-12."
Idaho Regulatory Agencies	17718	53	Where did these percentages come from? They are used elsewhere in the text, but no reference is given. Please note that no regulatory agency has approved these estimates. Also it should be stated as " <i>concurrent with mining....</i> " Also, it would be accomplished during Closure and Reclamation.	MIN	These percentages come from the Reclamation Closure Plan. Text revised to clarify that the percent of concurrent reclamation is proposed.
Idaho Regulatory Agencies	17718	54	The heading is "Stibnite Gold Mitigation Plan," but topic sentence of first paragraph is about the basis of proposed Environmental Design Features (please spell out, especially when first used in a section). 1. There is more than one Mitigation Plan, correct? If so, then heading should be "Plans". 2. topic sentence should introduce the concept of environmental mitigation . As written, this section is about proposed EDFs.	MIN	The sub-components of the Stibnite Gold Mitigation Plan are described within the Section 2.4.9.2 text.
Idaho Regulatory Agencies	17718	58	This paragraph is difficult to understand, please consider a rewrite. [For reference section: Hall, B., 2014. Cut-off Grades and Optimizing the Strategic Mine Plan. Australasian Institute of Mining and Metallurgy, Print Book, English, 300 pages.]	MIN	Comment noted, no revisions made.
Idaho Regulatory Agencies	17718	59	This paragraph is difficult to understand; please consider a rewrite.	MIN	Comment noted, no revisions made.
Idaho Regulatory Agencies	17718	62	This paragraph is difficult to understand, please consider a rewrite.	MIN	Comment noted, no revisions made.
Idaho Regulatory Agencies	17718	64	Should be <i>Off-site Gold Processing Alternative</i> . However, later, the statement is made that there is no mill in the western US that can economically process the Project ore. This is correct, because there is no mill to deal with the Antimony. There exists a number of mills that can process refractory gold in northern Nevada, which is what Barrick looked into many years ago. Therefore, the topic sentence should be: <i>The off-site ore processing alternative was examined and eliminated.</i>	MIN	Revision made per comment.
Idaho Regulatory Agencies	17718	65	Should be <i>Filtered and Paste Tailings Alternative</i> - because the term Dry stack tailings is a misnomer and should not be used : they typically contain moisture contents of 20% or more. They are not dry.	MIN	Text revised to clarify that the term Dry Stack tailings is used synonymously with filtered tailings.
Idaho Regulatory Agencies	17718	154	Current text: "Runoff from haul roads and access roads outside of pits... the protection of surface water quality". If storm water control measures includes storage of water in excess of 24 hours a water right would be required, including mitigation.	MIN	The water right requirement associated with storage of water for more than 24 hours was incorporated in a previous section. This is also covered in Section 3.8.4.2.
Idaho Regulatory Agencies	17718	155	Current text: "An additional total of 0.28 cfs of groundwater rights needed..." Our records indicate that Perpetua applied for four ground water rights totaling 0.34 cfs. Explain the discrepancy.	MIN	Revision made per comment.
Idaho Regulatory Agencies	17718	160	Provide a brief narrative why/how the 24-hour Probable Maximum Precipitation was selected/determined. Was snowpack considered?	MIN	Snowmelt was considered in developing the Probable Maximum Precipitation (PMP) event. However, the greatest PMP was determined to occur during non-snowmelt months based on use of standard method HMR-57.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Idaho Regulatory Agencies	17718	163	Current text: "...payable to IDWR to ensure the TSF is placed in a safe and maintenance-free condition upon decommissioning." Add: or if abandoned by the owner (see comment below)	MIN	Revision made per comment.
Idaho Regulatory Agencies	17718	164	Current text: IDWR also would require a bond so that the TSF can be placed in a safe maintenance-free condition if abandoned by the owner. Change to something like: IDWR also would require a bond so that the TSF is placed in a safe maintenance-free condition upon decommissioning or if abandoned by the owner.	MIN	Revision made per comment.
Idaho Regulatory Agencies	17718	166	Current text: "Perpetua would restore appropriately designed meandering stream channels (Meadow Creek and tributaries) within a stream and floodplain corridor across the top of the lined TSF surface (Rio Applied Science and Engineering [Rio ASE] 2021). Pools and riffles would be constructed within the channel. As previously commented (previous DEIS versions/technical reports and to the Project Proponent directly), IDWR is not categorically opposed to this concept, but clarified that routing a perennial stream over a TSF is unusual. Ultimately the TSF needs to be in a safe maintenance-free condition in the long term.	MIN	Comment noted.
Idaho Regulatory Agencies	17718	167	General comment regarding the TSF: IDWR will conduct a detailed review of the TSF once an application is submitted. Some of the SDEIS includes some general aspects of the design, but not in sufficient detail to provide technical comments.	MIN	Comment noted.
Idaho Regulatory Agencies	17718	161	Add a paragraph how the PMP/PMF was considered in terms of designing the TSF to contain the volume of water from the storm event including freeboard.	MIN	The incorporation of the PMP into the TSF capacity was described in SDEIS Section 2.4.5.8.
Idaho Regulatory Agencies	17718	162	Based on information provided on page 2-62 the diversions around the TSF will be designed to convey flows from a minimum 100-year storm event with 1 foot of freeboard. Is the assumption that during the PMP/PMF event these diversions fail and do not diminish flows on top of the TSF? Include a brief discussion to clarify.	MIN	The description of the Meadow Creek diversion channel around the TSF and TSF Buttress indicates its design size but makes no assumptions regarding failures during PMP/PMF events. As a description of the Project as proposed, no clarification has been added.
Idaho Regulatory Agencies	17718	165	IDWR also would require a bond so that the TSF can be placed in a safe maintenance-free condition if abandoned by the owner.	MIN	Comment noted.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	18649	4	<p>I have personally managed the evolution of the original proposed action to the Preferred Alternative now appearing in the SDEIS for public review. The resources and expertise dedicated by Perpetua to making the 2021 MMP the quality action alternative speaks for itself but does not, alone, provide the full picture of Perpetua's dedication to make the Stibnite Gold Project the best it can be economically and environmentally.</p> <p>To be clear, the SGP is a mining project lawfully anchored in the 1872 Mining Law. Just as the Clean Air Act, Clean Water Act and Endangered Species Act are longstanding expressions of legal authority set forth by Congress, so too is the 1872 Mining Law. But the Stibnite Gold Project is not proposed to be constructed in a National Park or in the heart of Idaho wilderness. Rather, it is proposed to operate squarely in a contaminated, legacy area of Idaho left abandoned and neglected by the Federal government.</p> <p>The Project designers inherited an environmental underpinning to build an operating mine that at best can be described as dreadful. The SDEIS at E-5 so concedes the challenge: "Currently, there are ongoing releases of hazardous substances, pollutants, and contaminants to surface water and groundwater at the site including elevated concentrations of antimony, arsenic, copper, lead, mercury, and cyanide. Most notable are elevated concentrations of arsenic and antimony." From the start, the Project had to address these legacy conditions with the full understanding that the magnitude of legal permitting and subsequent compliance would have to be accounted for in the development of the NEPA proposed action.</p> <p>As the data was collected and analyzed, no one on my Permitting Team ever deferred diligently working through what we were understanding from the modeling and then translating the results into a better Project design. The comments we reviewed from the DEIS only spurred us to double down on our efforts. Perpetua will be separately providing comments on the particulars of the environmental improvements and Project efficiencies in the Preferred Alternative, but the Company was relentless in</p>	MIN	Comment noted.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			searching for and crafting solutions to the environmental problems we encountered beginning from the original Plan of Restoration and Operation to the 2021 MMP.		
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	43	Existing Versus New Stream Crossings from Mine Access Roads Throughout the DSEIS, the number of estimated stream crossings for mine access roads are compared between the alternatives, but the context of these stream crossings (i.e., existing versus new) is not generally included in these analyses. For example, new stream crossings where a road did not previously exist has a different impact than reconstruction of current road stream crossings to higher environmental protection standards which may result in an improvement of aquatic conditions/upstream access. Where appropriate to meaningfully distinguish impacts between alternatives, in addition to estimated number of stream crossings, EPA recommends the FEIS evaluates the potential impacts from stream crossings that considers potential different responses associated with existing stream crossings and new stream crossings.	MIN	Effects associated with road crossings (e.g., runoff, sedimentation, spills) would occur as a result of Project road usage regardless of whether these crossings were existing or new because the nature and extent of new traffic. Further, many existing crossings would be upgraded to accommodate that traffic. Therefore, the effects analysis does not differentiate between new and existing crossings because of the effects associated with increased usage.
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	66	Ore Processing <ul style="list-style-type: none"> The DSEIS indicates grinding will occur within an enclosed building to reduce noise levels and facilitate maintenance of the milling equipment. EPA recommends the FEIS confirm if the ore processing building will be enclosed, and if not, correct its description throughout the FEIS. EPA notes a similar statement regarding an enclosed ore processing facility building is included in the Environmental Design Features on page 2-112. The DSEIS indicates the limestone crusher, screens, conveyors, and feed bins would not be enclosed. Dust would be controlled in a similar manner to the ore crushing and conveying process using water sprays and/or bag house dust collectors. EPA recommends FEIS confirm if the limestone processing would be controlled like the ore processing operation, and if so, correct its description throughout the FEIS. 	MIN	The Project description regarding enclosures of the ore processing activities is based on the Project proposal. The Final EIS continues to specify the enclosed or unenclosed location of these activities.
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	67	Tailings Storage Facility <ul style="list-style-type: none"> Regarding “[t]he TSF would be designed and operated as a closed-circuit, zero-discharge facility meaning no tailings water would be discharged to the surface water or groundwater except in compliance with applicable permits and regulations” and “[w]ater from the TSF and TSF Buttress underdrains may be discharged from two outfalls shown on Figure 2.4-15,…” <p>The first sentence implies that there will be no discharge from the TSF. Based on the other two sentences, this appears to be accurate for operational conditions, but not for closure. Therefore, for the FEIS, EPA recommends revising the first sentence as follows: “… no tailings water would be discharged during mining operations,…”</p>	MIN	Revision made per comment.
Small, Nathan (Chairman, Fort Hall Business Council, Shoshone-Bannock Tribes)	18903	34	All synthetic liners or lining material should be 80 ml HDPE and not LDPE. LDPE will not withstand the weight and usage common at a mining operation. 80 ml HDPE liner should be seam heat welded. Even though the Idaho regulations for cyanide processing do not require this, please raise the bar for mining practices in the US by foreign companies.	MIN	The Project proposal specifies the use of HDPE for liners except for the TSF liner which uses 60-mil linear low-density polyethylene over a geosynthetic clay liner per IDEQ requirements.
Small, Nathan (Chairman, Fort Hall Business Council, Shoshone-Bannock Tribes)	18903	50	Process flow diagram(s). Please show and label the cyanidation component of the ore processing.	MIN	Cyanide would be present in the ore processing where process water would be in use, i.e., all locations from the SAG Mill through the remainder of the process.
Michael Spicher (Engineering)	19040	3	The updated mine plan in the 2020 feasibility study, on which the 2021 MMP is based, included extensive modifications to the mine schedule, dump and open pit configurations which offer a number of environmental and operational advantages. The USFS has appropriately identified that the stockpiling strategy would "increase utilization of the mineral resource" (SDEIS 4.2.2.2). The stockpiling strategy	MIN	Comment noted. Statement of Position.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Manager, Integra Delamar)			also has the effect of keeping lowgrade mineralized material out of the waste rock dumps resulting in reduced metals leaching potential and an overall reduction of waste rock volume, as lower grade material mined early in the project is ultimately processed rather than wasted. This, coupled with the plan to reduce the size of the Hangar Flats open pit, allowed for elimination of the Fiddle waste rock storage facility. The reconfiguration of the TSF buttress waste rock dump, in which waste rock is placed along the northeast side of the valley, allows for a longer length of stream habitat below the buttress relative to prior configurations. These key project modifications allowed the USFS and Perpetua to address stakeholder comments regarding project footprint while improving project economics and operational feasibility through increased gold production and reduced water management requirements.		
Michael Spicher (Engineering Manager, Integra Delamar)	19040	4	The current mineral process circuit flowsheet and operating conditions, have been tailored to reduce potential environmental project impacts while achieving high gold and antimony recoveries, as detailed extensively in the feasibility study metallurgical testwork and summarized in the SDEIS. The addition of limestone to the process circuit has three advantages; first, it achieves desired pH and rheology conditions for gold deportment; second, it avoids the need to truck lime to site decreasing haulage traffic; and third, it reduces the formation of soluble arsenic compounds through formation of crystalline compounds. Furthermore, pH-temperature stability testing conducted for the feasibility study showed that POX discharge neutralization carried out in two stages better preserves the stability of the ferric arsenate precipitate. This recognition spurred Perpetua to propose the hot arsenic cure process if needed. Arsenic stability was not identified as an issue in the DEIS, or by project opponents; the company undertook the additional metallurgical testing on its own volition in recognition that it could be problematic environmentally. Overall, the extensive testing conducted by Perpetua to improve the overall geochemical stability of the tailings in the TSF, and use of locally sourced limestone, is representative of the company's commitment to environmentally responsible mining practices and common sense design principals. The Supplemental DEIS should appropriately recognize and acknowledge the overall geochemical and traffic-related benefits of the updated mineral process flowsheet.	MIN	Comment noted. Statement of Position.
Joseph Pietri	19062	19	TSF- In attending the USFS/Perpetua presentation at the Best Western McCall this past Fall I was astonished how many questions Perpetua was unable to answer. Most disturbing was the question of thickness of membrane for the Tailings pit. The person that to me would be Knowledgeable could not answer that simple question nor could anyone else. Is a 60 Mil membrane is that sufficient	MIN	The Project proposal specifies the use of HDPE for liners except for the TSF liner which uses 60-mil linear low-density polyethylene over a geosynthetic clay liner per IDEQ requirements.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	67	*** <i>The East Fork South Fork Salmon River Tunnel would only be utilized as a contingency to manage high flows upon completion of the restoration of the East Fork SFSR across the backfill in the Yellow Pine Pit.</i> " The annotation on the EFSFSR Tunnel is incorrect. While true for a specific period of time during reclamation of the YPP, it is not an applicable notation to this figure which includes the mine site layout. Please remove.	MIN	The annotation has been removed from the legend.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	29	" <i>Under the 2021 MMP there would be approximately 278 acres of unreclaimed pits/highwalls.</i> " This total appears to include 13 acres of project -related surface disturbance reclaimed as ponds (Stibnite Lake and Midnight Pond). Please revise or clarify, if applicable.	MIN	The acreage does include those areas that have not been reclaimed but remain as new features post-closure.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	31	" <i>Dewatering of the pits would lower groundwater levels in the alluvial and bedrock formations during the mining and post closure periods and would reduce flows in local surface water streams that receive groundwater discharge.</i> " There will be no post-closure pit dewatering; therefore, groundwater levels in proximity to the pits will recover during closure. Please replace " mining and post closure periods " with " mining period "	MIN	No revision made. The dewatering of pits would reduce water levels into the post closure period until water levels recover.
Ruth Lewinski	19378	10	4.0 Further Exploration	MIN	Exploration activities are a component of the 2021 MMP for its proposed duration.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			Several sites at the Stibnite Mine are discussed to be available for further exploration. While the initial project and permitting process is published in the context of a 40-year operation, the proposal for further exploration does not have a clear outline. This discussion is vague and communication about the potential time [auto-markup:Request for Comment Extension]extension[auto-markup end] of mining in the area is not appropriately disclosed.		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	164	<p>5. Arsenic in ore</p> <p>The largest component of total on-site arsenic (64%) is in ore. Under the SDEIS preferred alternative, a projected 112 million tons of pit ore will be produced, containing 396,246 to 1,028,406 tons of arsenic (average - 95th percentile). Ores will be crushed and ground and subjected to flotation concentration. About 85% of arsenic in ore will go to concentrates and 15% to tailings. Neither the DEIS nor SDEIS addresses the arsenic content, geochemistry or chemical constituency in relation to these proposed metallurgic processes or waste characteristics. This omission is of considerable concern, as arsenic chemistry and toxicity are complex and species (valence) dependent. Solubility, bioavailability and toxicity are highly variable among mineral processing applications depending on other metal concentrations, pH, and oxidation-reduction status, among other factors. There are additional issues regarding the soluble arsenic in the TSF discharge, uncertainties and lack of reliability in arsenic stabilization, reliance on inappropriate leachate tests, and TSF leak detection and treatment (described further in von Lindern/TIFO, 2023). The Forest Service should not accept Perpetua's assertions that arsenic in the TSF discharges can be stabilized, and consider an Alternative that does not require on-site treatment and disposal of thermally treated arsenic.</p> <p>In summary, the SDEIS does not do a sufficient job of characterizing how toxics such as arsenic will be managed under the preferred alternative and mitigating for the expected effects. We urge the Forest Service to rectify these issues in a revised SDEIS.</p>	MIN	Arsenic in ore would be managed by placement in the lined TSF facility. The environmental effects of this placement are described in SDEIS Section 4.9.2.2.
David Chambers	17634-A	3	The second serious flaw in the technical analysis is failure to include technical reference documents containing preliminary technical specifications and analysis of the tailings dam. The SDEIS refers to calculated factors of safety for both static and seismic considerations, provides the updated seismic risk analysis necessary to make these calculations, but is still lacking the basic engineering specifications for the dam itself. For example, there is no discussion of the fundamental type of dam construction (downstream or centerline?), the specifications for the fill for the different sections of the dam, and how the quality assurance for dam construction will be performed. Developing this information is standard procedure for an EIS, and since the fundamental dam design does not appear to have changed since at least 2017, there should have been more than sufficient time to develop this information.	MIN	The IDWR is the proper authority in Idaho to regulate design, construction and operation of dams, including tailings disposal facilities. These requirements are cited in Section 3.2.3 of the EIS. Perpetua would need to comply with the IDWR regulations and requirements for its TSF. The monitoring requirements for the TSF would be established by the IDWR permitting process and the Forest Service recognizes the primacy of the IDWR in these matters, so therefore has not specified monitoring of the TSF in the EIS. USFS monitoring of the TSF structure would be limited to reclamation.
David Chambers	17634-A	6	<p>2.4.5.8 Tailings Storage Facility</p> <p>The design, construction, operation, and closure of a tailings facility, primarily the tailings dam itself, is the most important mine-related structure to be analyzed in an EIS because of the potential environmental, economic, and public safety liabilities associated with a structure that must function properly for millennia. In a worst-case accident, tailings would be released causing environmental harm, the loss of property, and the loss of life.</p> <p>Normally the references for an EIS would include a technical report from an engineering company experienced in the design, construction, operation, and closure of tailings dams. The SDEIS references do not include such a report. The SDEIS refers to the Feasibility Study (M3 2021) for many of its technically related comments on the tailings storage facility, but the feasibility study1 itself does not contain technical information on the tailings dam.</p> <p>The figures presented in the SDEIS, Figures 2.4-10 and 2.4-11, suggest that at least some preliminary engineering work has been performed, but there is no reference given for the source of these figures, which by themselves are wholly inadequate to permit the construction of a tailings dam. These figures also appear in the Feasibility Study (M3 2021), which contains a figure not included in the SDEIS, Figure 18-11 (M3 2021). Figure 18-11 is a cross section of the dam showing Zone B Fill and Zone C</p>	MIN	<p>The IDWR is the proper authority in Idaho to regulate design, construction and operation of dams, including tailings disposal facilities. These requirements are cited in Section 3.2.3 of the EIS. Perpetua would need to comply with the IDWR regulations and requirements for its TSF. The monitoring requirements for the TSF would be established by the IDWR permitting process and the Forest Service recognizes the primacy of the IDWR in these matters, so therefore has not specified monitoring of the TSF in the EIS.</p> <p>As depicted in SDEIS Figure 2.4-10, TSF embankment construction would be classified as downstream construction.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>Fill, which constitute the major structural zones of the dam – but there is no explanation of how these zones will be constructed.</p> <p>We do not know whether this dam would be classified as a downstream or centerline construction type. We do not know what type of stability analysis has been done on the dam, if any. Golder (2021) provides some of the information needed to perform this stability analysis, but does not discuss the stability analysis itself. This is critically important information, and should be included in the SEIS.</p>		
Samuel Penney (Chairman)	19396	53	<p>2.7 Agency Preferred Alternative</p> <p>Where is the engineering design plan for the tailings storage facility? There should be more details disclosed for the design and building of the large buttress and storage facility in upper Meadow Creek.</p>	MIN	The IDWR is the proper authority in Idaho to regulate design, construction and operation of dams, including tailings disposal facilities. These requirements are cited in Section 3.2.3 of the EIS. Perpetua would need to comply with the IDWR regulations and requirements for its TSF. The monitoring requirements for the TSF would be established by the IDWR permitting process and the Forest Service recognizes the primacy of the IDWR in these matters, so therefore has not specified monitoring of the TSF in the EIS.
Samuel Penney (Chairman)	19396	56	<p>Inadequate Description and Environmental Analysis of Mining Process, Storage, Closure, and Reclamation</p> <p>According to SDEIS Section 2.4.5.7 Ore Processing, “[t]he gold and silver concentrations of the tailings would be regularly monitored and, if the concentrations are high enough to warrant further processing, they would be sent to the leaching circuit; otherwise, the tailings would be thickened and neutralized then routed to the TSF as described below.” This statement suggests that the pressure oxidation and cyanide leaching circuit will be sized to handle the full ore stream; also, that the tailings, if not pressure oxidized and cyanide leached, would be neutralized, assumedly with respect to cyanide. It would be unusual if the process facility, primarily designed for pressure oxidation and cyanide leaching of flotation concentrates, would also have the option of pressure oxidation and cyanide leaching of the full ore feed stream as well. This might also be expected to alter the geochemistry of the tailings depending on the option used. It would be unusual for a flotation tailings to undergo neutralization for cyanide; this infers that the flotation circuit will include cyanide. The SDEIS should clarify the statement with regards to tailings processing and neutralization and if the option to process the full stream is planned, then the SDEIS should address to what extent it might impact tailings geochemistry.</p>	MIN	Process water would be primarily recycled from other locations in the process and would have the potential to require neutralization for cyanide prior to conveyance to the TSF. Characterization of tailings geochemistry incorporates the effects of cyanide in solution.
Samuel Penney (Chairman)	19396	57	<p>The potential for mercury to be collected by gold and silver cyanide leach carbon adsorption facilities in addition to its potential to become an environmental issue as a result in electrowinning and refining facilities is well established but should be further discussed in SDEIS Section 2.4.5.7.</p> <p>The SDEIS should discuss how the proposed process for the Project differs from that where the intermediate product from electrowinning has typically been treated in a low-temperature/negative pressure retort furnace for removal and capture of the majority of the mercury prior to refining. The proposed method appears to do this in one step. The SDEIS should identify the pros and cons of this approach with respect to removal and sequestration of mercury.</p>	MIN	Section 2.4.5.7 describes how ore processing utilizes electrowinning followed by a heated retort to collect mercury similar to the process described by the commenter.
Samuel Penney (Chairman)	19396	58	<p>SDEIS Section 2.4.5.7, Ore Processing is confusing and unclear as to whether additional treatment for residual cyanide, in addition to neutralizing within the ore processing plant to less than approximately 10 milligrams weak acid dissociable cyanide, will occur before the tailings slurry is placed in the TSF. The SDEIS should clarify that the thickener “underflow” after neutralization would have less than 10 milligrams cyanide as it is pumped/placed in the TSF. The potential for, and impacts from, a tailings spill containing up to 10 milligrams Weak Acid Dissociable cyanide should be included and analyzed as a real and foreseeable event in the SDEIS.</p>	MIN	<p>Section 2.4.5.7 describes the neutralization for cyanide. There would not be further neutralization aside from this description.</p> <p>Effects from spills of hazardous materials including process solution are described in SDEIS Section 4.7.2.2 along with spill response activities.</p>
Samuel Penney (Chairman)	19396	59	<p>The SDEIS provides limited information in Section 2.4.5.8 on the TSF with respect to the technical facets of the facility. No basis for the information is provided or referenced. In order to provide the necessary information for a NEPA-level analysis, it is necessary in the case of TSFs, and waste rock piles as well, to bring their detailed design to at least a 30% completion level, consistent with the American Society of Civil Engineers levels identified in the Reclamation and Closure Plan (“RCP”) and for TSFs a 90% completion level should have been performed if third-party review is intended. This information should have been provided as the basis for the mine application prior to initiation of the</p>	MIN	The IDWR is the proper authority in Idaho to regulate design, construction and operation of dams, including tailings disposal facilities. These requirements are cited in Section 3.2.3 of the EIS. Perpetua would need to comply with the IDWR regulations and requirements for its TSF. The monitoring requirements for the TSF would be established by the IDWR permitting process and the Forest Service recognizes the primacy of the IDWR in these matters, so therefore has not specified monitoring of the TSF in the EIS.

			<p>NEPA process. The Forest Service should consult other Regions as to the normal provisions in this regard, including for the Resolution Copper Mine in Arizona (Tonto National Forest) and East Boulder Mine Stage 6 TSF in Montana (Custer Gallatin National Forest), as well as other NEPA analysis where TSFs and waste rock piles are involved. A new SDEIS should provide the following for the TSF:</p> <ul style="list-style-type: none"> ● A probabilistic and deterministic seismic evaluation for the area (included but references labeled confidential). ● A dam breach analysis, a failure modes and effects analysis or other appropriate detailed risk assessment, and an observational method plan addressing residual risk. ● A description of the chemical and physical properties of the materials and process solutions to be stored in the TSF. ● A list of the assumptions used during the analysis and design of the facility and a description justifying the validity of each assumption. ● A description of proposed risk management measures for each facility life-cycle stage, including construction, operation and closure. ● A detailed description of how water, seepage, and process solutions are to be routed or managed during construction, operation and closure. ● A detailed description of stormwater controls, including diversions, storage, freeboard, and how extreme storm events will be managed. ● A flood event design criterion less than the probable maximum flood but greater than the 1-in-500 year, 24-hour event. ● Utilization of an Independent Review Panel to ensure the TSF design plans satisfy Best Available Technology. <p>The SDEIS descriptions of the TSF in terms of design basis, geotechnical conditions, geohazard conditions, liner, cover, reclamation and closure, anticipated construction and third-party oversight, and other facets typical and necessary to understanding a proposed project and evaluating its potential environmental impacts are inadequate. Other than with respect to reclamation and closure no basis for the information is provided or could be identified by searching the public available references. The SDEIS should be supplemented and reissued for public comment with a more complete description of the TSF (and waste rock piles) and provide the basis for, and public access to, the technical documentation that supports the description and any analysis in the SDEIS.</p>		<p>Dam breach and failure mode analyses are not required to satisfy NEPA requirements because they represent a worst-case scenario that is not reasonably foreseeable.</p>
Samuel Penney (Chairman)	19396	62	<p>According to SDEIS Section 2.4.5.15 Temporary Closure of Operations, during any temporary shutdown, the operator would continue to implement operational and environmental maintenance and monitoring activities to meet permit stipulations and requirements for environmental protection. If ore processing is not occurring, excess water collected from the various facilities would need to be discharged to the TSF for storage. In the case of a longer-term closure, water treatment could be necessary to allow discharge to the area streams and prevent filling of the TSF.</p> <p>A plan would need to be developed, reviewed and approved by the appropriate regulatory authorities, and implemented at the time of any longer-term temporary closure. In the event of temporary closure, particularly if as a consequence of bankruptcy of the operator, a plan to implement ongoing operations so as to continue to meet environmental protection measures should be required and included with the reclamation plan. Once a temporary closure occurs measures must be implemented immediately - it is too late to implement a plan that has not even been developed, including for long-term measures. Temporary closure should be considered as a part of the design, and not in reaction to circumstances when it is too late or difficult to easily implement mitigation measures.</p> <p>The temporary closure of operations is typically described in an Interim Emergency Water Management Plan that provides information to the regulatory agencies on how process water systems, interceptor wells, seepage collection systems and stormwater management systems are operated and maintained to prevent discharges in the event the department assumes management of the mine facility. The plan typically includes process water flow charts showing electrical system requirements, pump operations, seepage collection and interceptor well operations and applicable operation and maintenance requirements. Temporary Closure of Operations should be</p>	MIN	<p>Water management under emergency shutdown conditions is described in the Project's Water Management Plan.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			addressed and detailed information provided in an Interim Emergency Water Management Plan and referenced in the SDEIS.		
Samuel Penney (Chairman)	19396	64	<p>According to SDEIS Section 2.4.7.4 “A low permeability geosynthetic liner would be incorporated into the cover over the entire surface of the backfilled Yellow Pine pit, including the re-constructed channel floodplain corridor to reduce the infiltration of meteoric water into backfill material, which could dewater the restored stream channel and result in additional metal leaching from the underlying backfill. Above the geosynthetic liner in the stream corridor, a layer of relatively fine material would be placed to protect the stream liner from puncture, followed by coarse rock armor to protect from exposure via stream scour, followed by floodplain alluvium at a minimum thickness equal to the maximum estimated scour depth of the proposed stream channel. Growth media would then be placed and the area revegetated. The lined corridor would be wide enough to accommodate future channel migration, evolution, and over-bank flooding.” The use of a low permeability geosynthetic liner is also described in Section 2.4.7.6 for the TSF and in Section 2.4.7.7 for the Hangar Flats Pit.</p> <ul style="list-style-type: none"> • The SDEIS and ModPRO2 do not provide additional details on the proposed liner system, the extent and nature of which appears to be entirely if not highly untested. The SDEIS should have taken a hard look at the proposal, including the extent to which a similar system has similarly been applied and used in what will be an geomorphologically active stream channel. As a result, the liner system will have to withstand the test of time, including as the cover materials wear away, revegetation with rooting trees takes place, and ultimately when catastrophic storm events such as those which took place this past early summer in Montana occur resulting in areas of major river channel changes, other areas of deep incisions, and ultimately destruction of the natural river channel. The SDEIS must analyze and address what will be certain future natural events that will most likely result in severe compromise of the proposed cover systems. The Payette National Forest should consult with the Custer-Gallatin National Forest to learn more about what occurred in 2022 and get their input as to the necessity of the SDEIS to consider a similar event occurring at the proposed Stibnite Project. • The SDEIS should describe the details of the cover system in order that its effectiveness and other characteristics can be assessed. The SDEIS should address the expected efficiency and longevity with respect to maintenance and replacement of the cover system given it will be required to continue to operate as per design in perpetuity, and address/include mitigation in the event of the failure of the cover system. The DEIS should address the potential impacts to the cover system such as long-term consolidation of the waste rock piles leading to differential settling, tree roots, and other potential causes of compromise of the proposed cover system. 	MIN	<p>The expected performance and longevity of the restored stream channels are included in the Compensatory Mitigation Plan for stream restoration.</p> <p>A mitigation measure associated with funding for long-term maintenance of restored and reclaimed areas has been included in the Final EIS.</p>
Samuel Penney (Chairman)	19396	198	<p>The SDEIS states that “[t]he TSF would be designed and operated as a closed-circuit, zero discharge facility meaning no tailings water would be discharged to the surface water or groundwater except in compliance with applicable permits and regulations.” However, the bottom liner is modeled to leak consolidation water due to minor defects in the liner from 34.3 m3/year in Mine Year 1 to 402 m3/year in Mine Year 14387 from the TSF with elevated concentrations sometimes orders of magnitude in exceedance of the strictest water quality criteria concentrations of arsenic, antimony, mercury, and residual cyanide. It is unclear in the SDEIS whether the seepage rate is projected to continue increasing from Mine Year 15 to 22 prior to cover placement.</p>	MIN	<p>Discharges are not part of the TSF design. The effects analysis for water quality in SDEIS Section 4.9.2.2 accounts for potential leakage from the tailings facility and the potential effects of leakage on water chemistry.</p>
Samuel Penney (Chairman)	19396	203	<p>The SDEIS does not explain how the bentonite layer will stay hydrated after being unrolled while exposed and not subject to a confining load, even while covered with a layer of High-density Polyethylene (“HDPE”). In addition, while HDPE does have good UV resistance, how is it determined whether the HDPE remains flexible and sturdy enough before filling with tailings to support a confining load after tens of years exposed to adverse environmental conditions on the perimeter of the TSF where tailings have not yet been deposited? It is required that HDPE be used in the cyanidation process,³⁹⁴ but sturdier products such as reinforced polyethylene have been developed which are a better choice for chemical and ultraviolet resistance, and flexibility to prevent cracking from the weight of tailings.</p>	MIN	<p>The Project proposal specifies the use of HDPE for liners except for the TSF liner which uses 60-mil linear low-density polyethylene over a geosynthetic clay liner per IDEQ requirements.</p>

Samuel Penney (Chairman)	19396	331	The SDEIS inadequately details maintenance work that will occur on roads associated with the Project. General discussions on graveling, grading and routine road maintenance are discussed throughout the document, however a detailed road maintenance plan describing specific activities and frequency of these actions was not found in the SDEIS. A maintenance plan is critical to understand resource impacts related to roads. The improvement work that will occur to existing roads needs to be quantified, and maintenance plans for all roads associated with the Project need to be established and included in the FEIS.	MIN	Road maintenance activities are described in the Transportation Management Plan which would be adopted as part of the Project upon the Forest Service's Project decision.
Samuel Penney (Chairman)	19396	442	Stibnite Gold Project Site-Wide Water Balance ("SWWB") Model Refined Modified Proposed Action (ModPRO2) Report The SWWB report states "forced evaporation only operates in the summer months . . ." yet later in the paragraph it states, "evaporators turn on in March and run...". This appears to be inconsistent.	MIN	Comment noted. The description of the usage period for evaporators does not affect the impact analysis presented in the EIS.
Samuel Penney (Chairman)	19396	443	The SWWB states, "Water needed for ore processing above the water available from reclaim is termed additional water. Additional water needs are a direct result or prediction of the SWWB, and makeup water is sourced from stored MIW, dewatering, or freshwater supply." Figure 6-18 is the Additional Water Needs Boxplot, which based on the definition above would include the three sources. However, later in the next paragraph, it appears to discuss the freshwater supply shown for groundwater (Figure 6-19) and surface water (Figure 6-20). It is unclear if Figure 6-18 includes only the freshwater additional water supply or all the additional water supplies (ex. stored MIW, dewatering). It would be helpful to have similar plots as the groundwater and surface water plots for stored MIW and dewatering sources.	MIN	Comment noted. SDEIS Figure 4.8-3 describes the process water components including water supplied from wells and surface water diversion.
Samuel Penney (Chairman)	19396	444	Figure 6-24 shows Process Makeup Water Required660 (all sources) and Figure 6-25 shows TSF Reclaim to Process. It appears there is generally more than sufficient supply by the TSF Reclaim. Is this correct? Would the data from Figure 6-24 equal the sum of the data from Figures 6-18 (additional water needs) and 6-25 (TSF reclaim)?	MIN	As depicted in SDEIS Figure 4.8-3, there are periods of time where TSF reclaim, contact water, and dewatering production are sufficient to meet mill demand and other times when these sources need to be supplemented by wells and surface water diversion.
R. Skipper Brandt, Ted Linsely, Denis Duman		1	The National Environmental Policy Act (NEPA) helps ensure all proposed projects meet strict standards for environmental protection, Stakeholders, regulators and experts have now reviewed the Stibnite Gold Project proposal for six years and local, state and federal agencies have analyzed the project. In our experience, Perpetua Resources has been transparent and cooperative, providing information to us on a regular basis. We have been provided with detailed technical information on the tailings storage facility, water quality, restoration, safety and other project aspects when requested.	MIN	Comment noted.
Samuel Cousins		10	4. Net Effects of Over-Optimistic Mitigation Success. The Regulatory Requirements and the Forest Plan Requirements listed on Page 2.4.9 and Table 2.4-12 list numerous "Could Do" measures, "Should Do" measures, in addition to the more mandatory "Shall Do" measures. The reality is that only the "Shall Do" measures are likely to be implemented. The "Would Do" would only be implemented if certain conditions are met or not met. The "Should Do" items are basically wishes, and therefore optional. Therefore, Chapter 4 Consequences cannot assume that all Measures in all three categories will actually be implemented. It has to disclose which it assumes will occur, which it assumes will not, and which it is uncertain about. Otherwise, the Consequences analysis will be heavily slanted toward minimization of adverse effects. Therefore, the suite of mitigation measures proposed have a very high risk of very low success. The consequences to aquatic and fisheries will be at high risk of being catastrophic. The DSEIS analysis needs to better reflect probability of success in estimation of effects of mitigations.	MIN	Prior to a Forest Service decision on the Project, design features and mitigation measures are not described as "shall do" because the decision regarding these proposed activities is pending. Upon a decision, design features and mitigation measures become requirements associated with Project approval. Uncertainties associated with water quality are described in SDEIS Section 4.9.2.4 with mitigation measures designed to reduce uncertainties described in SDEIS Section 4.9.3.
Samuel Cousins		13	7. Electrical Transmission Line. The Perpetua Alternative 2 will add Water Treatment Plants that will require a new and upgraded transmission line into the mine complex from the Johnson Creek substation. The line will require maintenance in a remote, mountainous, high elevation area of burned and falling snags. Winter snowpack in harsh conditions will exacerbate the problem and its costs. Who will patrol and monitor the new line? Who will pay the predictable costs of maintenance and repair? For future replacement?	MIN	The costs associated with maintaining water treatment plans into the post-closure period to the point where water treatment is no longer required would be incorporated into the reclamation cost estimate and closure bond for the Project.
Marilyn Olson		2	Where is the Burntlog Maintenance Facility site going to be located? Will it be near this fen adjacent to Mud Lake and decimated the rare plants at this location. Since this area along Burnt Log Road has	MIN	SDEIS Figures 2.4-5 and 2.4-8 depict the location of the Burntlog Maintenance Facility.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			unique wetland habitats, is it worth decimating a population of rare plantes to reconstruct a road through this area.		EIS Sections 3.10 and 3.11 describe the location of Project related disturbance outside of the Mud Lake areas and their associated vegetation.

Reclamation and Restoration

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Wasley, Dustin (Principal P.E., Haley Aldrich)	17633	2	<p>The reclamation and restoration projects inherent in the Stibnite Gold Project, especially addressing legacy AML issues are what really sets this project apart. Perpetua’s overarching goal in design of the project has been focused on restoration of the Stibnite mining district, and the company has planned and designed the mining operations and site closure with this goal in mind from the inception.</p> <p>Comprehensive cleanup of legacy mine wastes on the site achieved through private investment is the most notable aspect of the project. The extensive mining wastes present on the site exceed 10 million tons of materials and include tailings and waste rock, all of which currently contribute impaired water quality conditions, as appropriately noted in the SDEIS. Prior cleanup activities by various agencies have really only employed “band-aid” solutions. Perpetua’s plan to relocate historical mine waste materials to engineered waste rock facilities and reprocess historical tailings is the mining-scale solution required for the site and will successfully mitigate many of the current issues. Placement of spent ore materials in the tailings starter dam beneath the liner and use of engineered geosynthetic cover systems into the closure plan are solutions which have been shown effective in reducing infiltration and associated impacts to groundwater and surface water systems. Surface water and contact water management and treatment actions proposed during operations will effectively prevent additional contamination prior to facility closure. The proposed closure and reclamation plans have been successfully implemented at other site on FS-administered lands.</p> <p>Specifically, the Azurite Mine and the Monte Cristo Mining Area in Region 6 are two examples of successful closure that I have personally worked closely with the FS.</p>	RES	Comment noted. Statement of position.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	26	<p>This is particularly important when it comes to the SDEIS’s failure to provide a financial assurance calculation, which is necessary to ensure that sufficient funds are available for reclamation in the event that the company files for bankruptcy or is otherwise unable to complete reclamation. It is important to disclose and analyze the assumptions that will be made in establishing the financial assurance, the amount of post-closure financial assurance needed to protect the public if water treatment is required beyond Mine Year 40.</p> <p>The Forest Service defers the financial assurance calculation until after the ROD, yet the information that is available at this stage of the mine design, and for the SDEIS analysis, is more than sufficient to analyze the reclamation and closure costs. In fact, those calculations have already been made in the Feasibility Study (M3 2021). The Forest Service has decided not to include them in the SDEIS. By doing so, the SDEIS fails to take a hard look at the financial assurance calculations for reclamation and closure costs at the proposed SGP, including those water treatment liabilities that may continue for an undetermined time.</p> <p>Geographical and temporal limitations in the effects analyses can result in both underestimated and unrealized significant impacts that will not be disclosed in the SDEIS. The Forest Service must expand the geographic and temporal scales of the analyses and disclose the potential impacts in a supplemental or revised SDEIS for public review.</p>	RES	Reclamation cost estimates and financial assurance decisions are conducted by the Forest Service in a separate administrative process outside the NEPA scope. This process coordinates with Idaho State regulatory agencies and their financial assurance requirements.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	33	<p>H. Failure to calculate the financial assurance for reclamation and closure</p> <p>The SDEIS fails to include an analysis of the financial assurance associated with reclamation and closure. The public is ultimately liable for this cost if the company cannot pay it, and it is liable for any difference between the amount established by the Forest Service for the financial assurance, and cost overruns of reclamation and closure that may occur. Cost estimates must be made conservatively in</p>	RES	Reclamation cost estimates and financial assurance decisions are conducted by the Forest Service in a separate administrative process outside the NEPA scope.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>order to protect the public.</p> <p>In the 2019 Prefeasibility Analysis, the cost estimate for the financial surety was \$66.5 million. In the 2021 Feasibility Study that cost estimate increased to \$100 million. This cost calculation is not included in the EIS analysis, only in the feasibility analyses, but it has potential significant financial impact on taxpayers and the public. There is no technical justification for delaying the analysis of these calculations, since the calculations have already been done. The public deserves to be able to comment on these calculations as a part of the EIS.</p> <p>In his Technical Report from the Center for Science in Public Participation (Chambers 2022), Dr. David Chambers provides an important perspective on bonding, starting with a citation from SDEIS 2-91:</p> <p>The SDEIS notes that, “Perpetua would be required to post financial assurance to ... provide adequate funding to allow the Forest Service to complete reclamation and post-closure operation, including continuation of any post-closure water treatment, maintenance activities, and necessary monitoring for as long as required to return the site to a stable and acceptable condition in the event Perpetua was unable to do so.”</p> <p>When mines are developed, financial assurance is required by federal land managers and many state regulatory agencies. Financial assurance is necessary to cover the cost of reclaiming the disturbed surfaces of the mine, and to pay for all post-closure requirements. In this case, a significant part of the financial assurance will be for the cost of water treatment.</p> <p>It is also important to note that the financial assurance does not cover the cost of a potential mine accident. The financial assurance only covers planned closure. The financial assurance requirement is important for several reasons. First, there have been numerous instances in virtually every state of mining companies filing for bankruptcy without sufficient financial resources to complete their reclamation and closure obligations. In these instances, the government regulatory agencies did not require enough financial assurance to cover the actual costs of mine closure. In British Columbia, it is estimated that the province holds over \$1 billion less than the full value for financial assurance required to reclaim BC mines. If the mining company cannot clean up and close the mine, then the public becomes liable either for the cost of cleanup, or for the environmental consequences of the damaged mine site.</p> <p>There is significant political pressure to keep the costs of these financial assurances as low as possible in order to enhance the economic viability of the mine. This has led to significant underestimations of the amount of financial assurance required to close a mine after a bankruptcy. Alaska, Montana, Nevada, South Dakota, and other states have been victims of this problem. In each instance, taxpayer dollars were required to augment inadequate financial sureties.</p> <p>Second, the amount of money required to close the mine and to perform post-closure water treatment can be enormous. The present financial assurance for closure of the Red Dog mine in Alaska is \$563 million, most of which is related to water treatment in perpetuity. At closure, the Red Dog Mine plans to treat approximately 1.8 billion gallon/year, which drives the majority of the financial assurance requirement. Perpetual water treatment at Stibnite would add hundreds of millions of dollars to the closure cost, which must be covered by the financial assurance.</p> <p>The method the agency uses to calculate financial assurance is an important issue that is not covered in the EIS. Public disclosure, and an opportunity to review the cost calculations, is not only appropriate, but the potential financial and/environmental impact on the public is also significant.</p> <p>The National Environmental Policy Act requires federal agencies to undertake a pre-action analysis in the form of an Environmental Impact Statement (EIS) of potential environmental impacts for “major Federal Actions” that may “significantly affect” the quality of the human environment. 42 U.S.C. § 4332(2)(C).</p>		
Bonnie Gestring (Northwest)	17634	34	The applicable version of the Code of Federal Regulations, Title 40: Protection of Environment defines “human environment” as: §1508.14 Human environment	RES	Reclamation cost estimates and financial assurance decisions are conducted by the Forest Service in a separate administrative process outside the NEPA scope.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Program Director, Earthworks) and seven others			<p>Human environment shall be interpreted comprehensively to include the natural and physical environment and the relationship of people with that environment.(See the definition of “effects” (§1508.8).) This means that economic or social effects are not intended by themselves to require preparation of an environmental impact statement. When an environmental impact statement is prepared and economic or social and natural or physical environmental effects are interrelated, then the environmental impact statement will discuss all of these effects on the human environment. (emphasis in original) If a financial guarantee is required to protect environmental values, like clean water and fish, then 40 CFR1508.14 clearly suggests that the significant financial assurance required by agency regulations should be evaluated in an EIS. When a federal agency intentionally decides to ignore analyzing the requirement for a financial assurance to protect the environment, the message it clearly sends is that it is not confident in its ability to defend its financial assurance calculations to the public. Deferring the analysis of the financial assurance requirement until later in the permitting process expedites the permitting process, as well as make it more difficult, if not impossible, for the public to review and comment on the adequacy of the financial assurance requirement.</p> <p>Reclamation and Closure costs are not only a significant factor for calculating the capital costs of a mine, but are also a potential major liability to the public if they are not properly calculated and managed. This means reclamation and closure costs could have a major potential impact on the economic environment of both the community hosting the mine, and the taxpayers who would be liable to pay the costs of reclamation and closure if the mining company becomes financially insolvent. Under the NEPA definition of “significant environmental impact,” the potential impacts of an inadequately calculated financial assurance for the reclamation and closure of this mining project could have significant economic, social, and environmental impacts. The financial assurance should be analyzed as a part of this SDEIS.</p> <p>In the SDEIS, it is important to disclose and analyze the assumptions that will be made in establishing the financial assurance, the amount of post-closure financial assurance needed to protect the public if water treatment is required beyond Mine Year 40. At a minimum, tens of millions of dollars are at issue.</p> <p>However, in the SDEIS it is noted: “Calculation of the initial bond amount would be completed following the Record of Decision (ROD) when enough information is available to adequately and accurately perform the calculation.” (SDEIS2022).</p> <p>The information available at this stage of the mine design, and for the SDEIS analysis, is more than sufficient to analyze the Reclamation and Closure costs. In fact, those calculations have already been made in the Feasibility Study (M3 2021). The Forest Service has decided not to include them in the SDEIS. By doing so, the Forest Service is playing a classic game of “hide the ball.”</p> <p>The DEIS for the Idaho Cobalt Project on the Salmon-Challis National Forest included a draft bond calculation of \$44 million dollars.</p>		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	125	<p>2. Water treatment in perpetuity will likely be needed unless proven otherwise</p> <p>As noted elsewhere, the Forest Service should assume that long-term water treatment will be needed beyond Mine Year 40 unless the actual post-closure seepage rates for both tailings drain down and buttress seepage are low enough and/or contain only low levels of contaminants that there is no possibility it will require long-term treatment. See technical reports from Dr. David Chambers of CSP2 and Dr. Ann Maest of Buka Environmental.</p> <p>We note that the Forest Service required a bond for 100+ years of water treatment for the Idaho Cobalt Project out of an abundance of caution even though the mine was designed to avoid the need for water treatment in perpetuity. The Boise National Forest erroneously assumed that the expansion of the Level 900 adit near Atlanta would be managed without long term water treatment. Now we have a situation where elevated arsenic levels require water treatment in perpetuity but the operator has been unable to comply with their Plan of Operations and NPDES permit and there is no bonding for water treatment in place. The Forest Service must avoid a similar situation here.</p>	RES	<p>Reclamation cost estimates and financial assurance decisions are conducted by the Forest Service in a separate administrative process outside the NEPA scope.</p> <p>Uncertainties regarding the duration of water treatment requirements would be incorporated into the reclamation cost estimate.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	126	<p>3. Reclamation cover materials are insufficient</p> <p>As noted elsewhere, we are concerned that the amount of cover/growth material available for reclamation is only 48% of the amount of material that will be needed (p. 4-87), assuming that the identified material will function as intended. As part of this analysis, a source for the additional required growth material is required. Delaying this commitment until a later time may result in a failure to find this material and a lowering of reclamation standards.</p>	RES	<p>The current Reclamation Closure Plan utilizes unconsolidated till materials mined from the Yellow Pine pit to meet the Project needs for growth material.</p> <p>The suitability of the Yellow Pine pit material as growth material would need to be verified and enhanced as necessary.</p> <p>Uncertainties regarding the sourcing of reclamation cover material would be incorporated into the reclamation cost estimate.</p>
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	128	<p>1. The SDEIS lacks detailed information about the reclamation and closure plan to analyze impacts</p> <p>According to Reclamation and Closure Plan (RCP) submitted by Tetra Tech (2021(b)) on behalf of Perpetua Resources “mining and reclamation plans are approximately 10 to 40 percent complete and have been established based on reasonable assumptions of technical, engineering, legal, operating, economic, social, and environmental factors.” (p. 1-23, emphasis added).</p> <p>The SDEIS must include a detailed reclamation and closure plan to demonstrate compliance with state and federal regulations and to provide sufficient information for decision-makers and the public to understand the potential impacts of the proposed project. This must include detailed engineering plans to describe all</p>	RES	<p>Sections 3.5 and 4.5 summarize the proposed reclamation plan and its effects. Detailed engineering plans are not required until facilities are closer to final closure.</p>
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	129	<p>2. The SDEIS identifies a vast deficiency in available reclamation materials and fails to demonstrate that timely reclamation can be achieved. The discussion in section 4.5.2.2 (SDEIS, p. 4-87) notes that the amount of cover/ growth material available for reclamation is only 48% of the amount of material that will be needed. Pages 4-85 identify the three primary challenges associated with the quality and suitability of available Reclamation Cover Materials (RCM) for the SGP: (1) the overall relatively poor existing quality of the upland soils that make up approximately 62 percent of the salvageable volume at the SGP and Burntlog Route; (2) the long-term stockpiling of material; and (3) the high background concentrations of metals in the soil. The SDEIS, on pages 4-85 notes that “options are being considered” to locate a source for the deficient material, yet no specific requirements have been incorporated in the SDEIS. Further, the Soils and Reclamation Cover Materials Specialist Report (p. 74) states that coarse woody debris would be scattered over reclaimed land, but offers no estimate of the total volume required or where it would be sourced.</p> <p>To address the deficit in reclamation materials, Perpetua proposes a number of potential options. Perpetua Resources anticipates that compost (and potentially other soil amendments) will be imported to the project site and applied to GM and YPP Till to improve their suitability. It proposes to import 13,850 tons of compost (RCP, p. 352) from dairy or feedlot operations (composted manure), which would be temporarily placed in stockpiles around the facility. The SDEIS fails to analyze the potential impacts of transporting and introducing large volumes of manure to the site, including the potential for the proliferation of weeds, and increases of nitrates and other nutrients in surface or groundwater. Further, the Soils and Reclamation Cover Materials Specialist Report (p. 74) dismisses the viability of this idea, stating:</p> <p>“The RCP identifies 10 tons per acre of compost would be incorporated into the top 3 to 6 inches of GM; however, the volume specified is minimal, translating to less than 0.25 inch of compost to be mixed into 6 inches of GM. This small amount of compost is not expected to provide sufficient long-term benefits to the GM that would be important for revegetation.” (Emphasis added)</p> <p>Similarly, Perpetua proposes to address the deficit of salvageable soil by bulking up the salvaged soils with wood chips to create “growth media” (GM). Depending upon a multitude of factors, the incorporation of wood chips into soil (particularly in the volumes proposed) can deplete plant-available nitrogen. The effects of anaerobic conditions expected in stockpiled GM (SDEIS, p. 46) on nitrogen cycling, microbial activity, and overall soil health should be evaluated in the context of wood chip addition.</p> <p>Even after the potential addition of wood chips, a GM deficit of roughly 800,000 cubic yards remains. The Reclamation Closure Plan (TetraTech, 2021a) proposes to use glacial till and colluvium/alluvium</p>	RES	<p>The requirements for reclamation cover materials and the sources of those reclamation cover materials are described in the Reclamation Closure Plan and summarized in Sections 3.5 and 4.5. The limitations on the soil available for salvage are identified along with the methods proposed to develop suitable cover material from other sources, namely mined till from the Yellow Pine pit, that meet suitability criteria.</p> <p>Effects of stockpiling on soil productivity are identified as a potential effect along with the management practices to minimize the effect.</p> <p>Reclamation and revegetation monitoring is described and would be used to assess reclamation performance per Forest Service reclamation requirements.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>from the Yellow Pine pit to make up the deficit. This solution does not appear to be analyzed in either the SDEIS or the Soils and Reclamation Cover Materials Specialist Report (U.S. Forest Service, 2022c). The Reclamation Closure Plan asserts that this material will be non-PAG/ML, but only provides average concentrations for arsenic, neglecting to mention antimony or mercury. Although the chemical suitability of this material is partially addressed, there is no mention of the other suitability criteria which likely rate it as fair to poor. This material would be stored separately from the other growth media, but it is unclear how it will be used. If it is blended with the other growth media when applied, this is likely to result in further decline in the suitability of already questionable quality growth media. There is no explanation why 1.5 million BCY would be stored in the Fiddle Growth Media stockpile when only 797,000 BCY are needed.</p> <p>To compound the soil quality and quantity deficits, the SDEIS identifies substantive impacts to soil viability from stockpiling soils for lengthy periods. According to the SDEIS (p. 4-86), these stockpiles would be up to 200 feet tall, and the time between GM salvage and placement would vary greatly between different SGP facilities but could remain in stockpiles for up to 42 years. The RCP (P. 3-55) states that soil productivity within the majority of the GM/SBM mass stored with stockpiles is expected to decline during the time of residence within stockpiles because, “Anaerobic conditions approximately 2 to 3 feet below the surface of the GMSs are anticipated to predominate and will likely lead to a decline in microbial respiration and a shift from an aerobic respiration endpoint of carbon dioxide to an anaerobic endpoint of anhydrous ammonia (NH3) or, depending on the soil moisture content, nitrogen gas or nitrous oxide.” The RCP proposes various mitigation measures to offset those impacts, but fails to demonstrate that these will be viable. In fact, the SDEIS (p. 4-87) concludes that, “Despite these measures, the storage of GM within deep stockpiles for years would still result in the loss of soil productivity, which would affect the overall quality of this material at the time of placement.” (emphasis added)</p> <p>The SDEIS must take a hard look at the potential impacts of stockpiling these materials and quantify the potential loss of viable soils for reclamation purposes and the adverse effects on reclamation efforts.</p> <p>The Executive Summary of the SDEIS (p. ES 11-12) identifies the uncertainty associated with sufficient quality and quantity of materials necessary for reclamation. “The overall relatively poor quality of the soils at the SGP mine site (outside of valley bottom soils), the long-term stockpiling of growth media (GM) or soil bank material, and the high background concentrations of metals in soils would affect the quality and suitability of available reclamation cover materials. GM used for upland reclamation sites would mostly come from relatively poor upland soils. Overall, the majority of GM used would rate as poor or fair (per suitability criteria), due primarily to texture and coarse fragment content (Tetra Tech 2019). These challenges, coupled with the harsh winter climate (short growing season) and generally steep slopes of the area, would compound the present difficulties in growing and/or maintaining persistent vegetation cover over reclaimed areas. This is consistent with the mixed vegetative cover success of nearby reclaimed mining areas and the previous efforts by Perpetua and others at the mine site to establish self-sustaining cover on previously mined lands that have had some limited success. Additionally, there would be a 797,702 bank cubic yards GM deficit at the mine site according to the balance calculations in the Reclamation Closure Plan. This deficit may be partially met with the surplus of material obtained from the Burntlog Route or could be met through additional composting of both on- and off-site soil amendments. Thus, there is presently some uncertainty regarding the specific source of material to meet the identified GM deficits under either action alternative. (SDEIS, p. ES-11)(emphasis added).</p> <p>Although the SDEIS states that Perpetua has committed to salvage the appropriate volume of GM and to create the volume of compost necessary as an amendment to provide suitable quality and quantity of the GM to cover the areas to be reclaimed, there is no data or analysis to demonstrate that this will be achieved. As noted in this and other sections, the proposed plan does not demonstrate that suitable soils will be available, mitigation measures will successfully offset the impacts of stockpiling soils, or that measures are in place to adequately address the high metal concentrations in soils. Furthermore, the SDEIS fails to take a hard look at the potential impacts to soils from climate change.</p>		

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>The SDEIS (p. 4-79-80) highlights the long-term harm to soil resources, stating that “this analysis assumes recovery of greater than 40 percent soil productivity of natural background within a 50-year timeframe would not occur (due to the nature of disturbance and the conditions at the site) and, therefore, the duration of impacts would be longer-term, well beyond the 50-year threshold.” And “For the TSF and TSF Buttress, where selected development rock would serve as the rooting zone for reclamation-related planting instead of native regolith, recovery of soil productivity to 40 percent of natural background would be on a much longer timescale (e.g., likely centuries to millennia) such that they would be considered permanent TSRC.” (emphasis added).</p> <p>According to the SDEIS (p. ES-11) Total Soil Resource Commitment (TSRC) is the conversion of a productive site to an essentially non-productive site for a period of more than 50 years. Productivity of these areas range from 0 to 40 percent of natural background.</p> <p>According to the SDEIS (p. 4-78-79), “Reclamation challenges associated with mine facilities are consistent with observations of nearby, previously reclaimed mining areas having mixed vegetative cover success (e.g., Dewey Mine/Thunder Mountain Mining District), as well as previous efforts by Perpetua and others at the SGP to establish a self-sustaining cover of vegetation on previously mined lands that were met with limited success (Greystone 1994). To conservatively address uncertainty in reclamation success, this analysis of Total Soils Resource Commitment (TSRC) assumes that all SGP-related disturbances in the PNF activity area would be considered TSRC due to the site-specific challenges and the duration and nature of soil disturbance to support the mining activities.” (Emphasis added)</p> <p>Section 4.5.2.2 identifies that the TSRC guidelines in the Payette National Forest Plan to limit TSRC to 5% of the activity area will be violated with the project-related impacts leading to a TSRC of 17% (approximately 1,457 acres). (SDEIS Table 4.5-1 and Figure 4.5-1). Rather than requiring the project to comply with the Forest Plan, the Forest Service is proposing a Forest Plan Amendment (FPA) which would waive the TSRC guidelines. By waiving the TSRC guidelines, and thereby authorizing a 17% loss of TSRC, approximately 1,457 acres of the project area will be converted from a productive site to an essentially non-productive site for more than 50 years. The SDEIS must specify how the loss of 17% of TSRC in the project area (approximately 1,457 acres) - resulting in the conversion from a productive site to an essentially non-productive site for more than 50 years — is consistent with reclamation goals, objectives, and requirements. The proposed plan, which includes a predicted 17% loss of TSRC, appears to treat the area as a sacrifice zone, without regard for reclamation requirements. Further, the SDEIS fails to take a hard look at the direct, indirect, and cumulative effects of the 17% TSRC loss on revegetation efforts, erosion, and other potential impacts. It also fails to consider the cumulative effects of these impacts, coupled with climate change.</p> <p>The proposed mine plan fails to demonstrate that available RCM will be of sufficient quantity or quality to achieve the reclamation objectives defined in the Reclamation and Closure Plan (Tetra Tech 2021a, p.1-1) of returning disturbed areas to productive conditions that sustain long-term wildlife, fisheries, land, and water resources. The proposed mine plan must demonstrate that suitable materials are available to complete reclamation. The SDEIS must specify where the reclamation materials will be sourced, including the quantity and quality of additional materials necessary for reclamation, and it must demonstrate that these soils can be stored and managed to meet reclamation requirements. The SDEIS must demonstrate that the proposed mine plan will comply with applicable state and federal requirements for reclamation and adequate protections of public health and environmental resources.</p>		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	130	<p>3. The SDEIS fails to take a hard look at the consequences of inadequate soil covers and reclamation materials, and provides inappropriate references to support cover depths</p> <p>The SDEIS fails to demonstrate that the proposed cover depths are adequate for reclamation purposes. The Reclamation and Closure Plan (p. 3-33) references a 2018 database of cover depths at Montana mines from the Montana Department of Environmental Quality to support potential soil depths for reclamation at SGP. However, two of the mines cited (Rock Creek and Montanore) have not been constructed, so reclamation success cannot be determined. Hecla withdrew its plan of operations for</p>	RES	Proposed soil cover thicknesses are described in the Reclamation Closure Plan and summarized in Section 4.5. Thicknesses are associated with proposed revegetation and are consistent with existing soil conditions in the Project area.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>those two proposed mines. The Montana Tunnels Mine, which is also cited, has not been successfully reclaimed. The mining company filed for bankruptcy in 2022, with substantive reclamation obligations unfulfilled and extensive erosion issues.169 The Graymont Mine is a limestone quarry, not a hardrock mine. These cited mines should not be considered suitable references for reclamation purposes at SGP.</p> <p>One consequence of the shortfall in growth media (GM) and seed bank material (SBM) volume is that the reclaimed areas have much less depth of GM spread over them than the depth of native material that is salvaged. For example, comparing numbers in Tables 3-5 and 3-7 in the Reclamation Closure Plan one can note that although salvageable SBM in wetlands extends to depths of up to two feet with another foot of suitable GM below that, the proposed application depth in all but one constructed wetland is a mere 2 inches of SBM over 4 inches of GM. It seems likely that the productivity and functionality of these thinly veneered wetlands would be significantly reduced from the existing areas, yet no analysis of the influence of soil depth on wetlands function is included.</p>		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	132	<p>5. The use of fertilizers may result in arsenic solubility in soils, and has not been adequately analyzed</p> <p>Fertilizer is considered another option for improving GM quality. However, there is disagreement as to how the addition of phosphate fertilizer might affect plant uptake of phytotoxic arsenic. The Reclamation Closure Plan (p. 3-57) suggests bioavailable arsenic could be reduced, while the Soils and Reclamation Cover Materials Specialist Report (p. 77) states that arsenic solubility could be increased. The SDEIS must address this inconsistency. Statistically robust greenhouse testing of the performance of the main reclamation plant species in phosphate amended GM should be required prior to field application of these fertilizers.</p> <p>As noted above, the Specialist Report (p. 77) finds that the use of chemical fertilizers is known to induce arsenic solubility in soils, and points to the use of fertilizers as one of the potential options identified by Perpetua in its RCP. The Specialist Report states that “Perpetua has identified some measures to limit the transport and exposure to soil-borne arsenic (e.g., surface water runoff routed to sediment basins, erosion-, sediment-, and dust-control best management practices, etc.)” However, there is no analysis to demonstrate that these measures would adequately limit the transport of soil-borne arsenic. The SDEIS must analyze the potential impacts of increased solubility, soil-borne arsenic, the potential mitigation measures, and the viability of these mitigation measures.</p>	RES	<p>SDEIS Section 4.5.2.2 describes the potential effects of fertilizers on arsenic solubility. However, the effects of arsenic solubility on plant uptake vary with plant tolerance observed in addition to phytotoxicity.</p> <p>The Final EIS describes a mitigation measure requiring the testing of fertilizers to assess their effects on metal mobilization prior to their use.</p>
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	133	<p>6. The suitability criteria for root zone materials fail to demonstrate that reclamation can be successfully completed or that public and ecological health will be protected It appears from the SDEIS (p. 87-88), that the reclamation plan proposes to use soils with up to 3,000 ppm arsenic as suitable root zone material (RTZ) for reclamation, and apply more restrictive, but not yet specified, criteria for growth media.</p> <p>The proposed concentrations for RTZ of up to 3,000 ppm are much higher than the existing concentrations for mercury within the project area that will be salvaged for reclamation (442 ppm arsenic, 0.82 ppm mercury, and 137 ppm antimony) or those from the SMUs (651 ppm arsenic, 0.96 and 379). (RCP p. 3-27 to 3-28). Thus, the SDEIS appears to authorize the use of soils for reclamation materials that will increase arsenic levels in soils within the area (i.e., worsen soil conditions).</p> <p>The Reclamation and Closure Plan (Tetrattech 2021) justifies the use of much higher arsenic concentration for Perpetua’s proposed suitability criteria based on Hecla reclamation effort from 1992. However, Hecla’s reclamation effort, analyzed in Appendix B, should not be used as the basis for developing suitability criteria because:</p> <ul style="list-style-type: none"> ● It relies on uncertain and unsubstantiated information: “Records, descriptions, or as-builts of the Hecla Reclamation are not available; however, based on communications with the exploration manager for Perpetua Resources, waste rock was nominally covered with one to two feet of “soil” of unknown origin and properties. Following this, seed was sown that included alfalfa (Medicago sativa), and two-to three-year old tree seedlings were planted. It is not known if amendments, fertilizers, or other cultural practices were applied to the site.” (RCP p. B-20) 	RES	<p>The suitability criteria for root zone material are based on the range of existing conditions for root zone material on site. As such these criteria are not reflective of average site conditions but rather the end of the range at which root zone materials are supporting vegetation. Previous reclamation results inform the criteria through observations of root zone materials that were revegetated and root zone materials that did not support vegetation.</p> <p>The Reclamation Closure Plan does propose suitability criteria for growth media in addition to root zone material.</p> <p>These suitability criteria for metals in growth media are based on current metal concentrations in Project area soils. A 2003 human health risk assessment concluded that existing site conditions did not represent a human health risk based on the likely exposure scenarios.</p>

			<ul style="list-style-type: none"> ● The conclusions of the HECLA Reclamation Area analysis concede that “In addition, intervening variables that were not quantified nor analyzed during this study may strongly influence or constitute the underlying causes for the correlations presented below and therefore the analysis should be understood as limited in these terms.” (p. B 3-5) ● It has not been peer-reviewed. ● It doesn’t provide data, or analyze potential public or ecological health issues associated with elevated arsenic concentrations. <p>Furthermore, the conclusions rest on the data from just three soil pits located in one of the oldest reclamation sites in the project area. Why weren't any of the other previously reclaimed sites such as the Spent Ore Disposal Area, the Garnet Pit, or any of the exploration phase test plots analyzed as well? Most of these sites are not doing very well as far as vegetation establishment (Soils and Reclamation Cover Materials Specialist Report, p. 77) Absent any rationale for site choice, this approach suggests a strong bias in site selection and sample number.</p> <p>The RCP describes the soils, with concentrations from 1,000-3,000 ppm arsenic as “poor,” with “severe limitations that make use questionable.” however it indicates that these soils could still be used in reclamation efforts. (RCP p. 3-25)</p> <p>Suitability criteria for reclamation cover material should be established, and identified in the SDEIS, including phytotoxicity concentrations that are based on well-established and conservative scientific analysis. These criteria should be focused on concentrations that facilitate reclamation objectives (e.g., prompt revegetation), not the upper bounds of what a plant might be able to tolerate. The suitability criteria must also take into account concentrations that are safe for public and ecological health. As stated in the EPA comments on the DEIS, “we are concerned that these values may not be protective of risks to surface waters and ecological receptors. The risk-based screening level (RBSL) values for mercury are 240 mg/kg. While this value was developed for soil ingestion RBSLs, impacts to proximate waterbodies at concentrations in this general range could be a significant issue. A mercury concentration of 240 mg/kg in reclamation cover material would be similar to the average concentration of mercury in tailings at the Cinnabar Mercury Mine (259 ±101 mg/kg), which is a significant source of mercury to downstream waterbodies. In addition, surface emissions to the air at concentrations in this range could become a significant source to the atmosphere that would need to be included in the emission estimates. The proposed cover material concentration of 240 mg/kg is three to four orders of magnitude above typical background soil concentrations presented in the draft EIS, which identifies a mean mercury concentration in soil samples collected from undisturbed areas surrounding the mine site of 0.94 mg/kg.”</p> <p>According to the SDEIS (p. 4-523), “Soils used for reclamation would be screened based on their concentrations of arsenic, antimony, and mercury to exclude materials with metal concentrations outside the range of natural baseline conditions or with metal leaching potential.” However, it doesn’t specify the concentrations that will be applied, and there doesn’t appear to be any metal leaching potential included in the SDEIS to support the criteria. The SDEIS should provide the metals leaching analysis, and demonstrate how this analysis is incorporated into the screening criteria.</p> <p>According to the SDEIS (P. 4-522), Idaho Department of Health and Welfare (IDHW) reviewed available information from the proposed Reclamation and Closure Plan for the SGP to consider whether potential health risks from metals in soils exist for future site users. The IDHW letter points to the suitability criteria proposed in the RCP, and finds that this range of arsenic concentrations exceeds human health screening values for metals in soils (Table 1). (IDHW, p. 2) It also finds that “Information on distribution of expected concentrations in metals or metal bioavailability across the reclaimed site is not provided.”</p> <p>According to the SDEIS, “The IDHW included recommendations for additional characterization to adequately assess risks to public health and recommended that potential human exposure following closure and reclamation should be considered when identifying RCM to ensure protection of recreational</p>		

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>receptors (IDHW 2019).” However, the SDEIS doesn’t indicate whether or how these recommendations will be included in the suitability assessment, or how they would be applied.</p> <p>The SDEIS fails to demonstrate that reclamation can be successfully achieved. The proposed suitability criteria are not supported by scientific literature, with arsenic concentrations that far surpass other phytotoxicity criteria established by the EPA, USGS and other governmental agencies. It proposes to use soils characterized under the suitability criteria as “poor” quality, without analyzing the effects on reclamation viability, and fails to consider the potential impacts to surface water or groundwater due to metals leaching.</p>		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	134	<p>7. Cumulative effects analysis of soils and reclamation is inadequate</p> <p>The cumulative effects analysis missed the following potential cumulative effects on soils and reclamation. It is reasonable to expect further soil disturbance from exploration activities subsequent to those permitted under the current Golden Meadows Exploration Project. Perpetua has stated their intent to continue exploration activities throughout the life of the mine and perhaps beyond. Once large mining projects are initiated, there is usually further development of ore targets (e.g., new or expanded pits and underground mining) identified through ongoing exploration activities. This would lead to further soil disturbance.</p> <p>One example of this is the fact that there is a high-grade ore target located below the currently proposed depth of the Hanger Flats pit (M3, 2021). If the price of gold increases, there are likely to be proposals to increase the pit size in order to access this ore. This would certainly cause further TSRC and DD impacts.</p> <p>Additional loss of soil will occur over the coming decades as the tops of the slopes above Blowout Creek (East Fork Meadow Creek) continue to erode backward. These slopes are currently at or beyond the angle of repose. Perpetua's planned treatment would not include laying them back to a stable angle, so the brows of the slope will continue to recede as erosion decreases the oversteepened slopes below.</p> <p>Further impacts to soil resources are reasonably foreseeable as a result of landslides and debris torrents. These disturbances are often triggered by rain-on-snow events which are expected to become more common as climate change increases the frequency and intensity of atmospheric river events (Espinoza et. al., 2018)</p> <p>The increased regulatory control on soil erosion cited as a mitigating factor (SDEIS 5.5.2) seems questionable given the possibility of reclamation failure due to the numerous post-closure revegetation challenges detailed above.</p> <p>Climate change presents yet another challenge to successful reestablishment of vegetation, and is only addressed in passing in the Climate Change Specialist Report (U.S. Forest Service (Forest Service), 2022b). Soil moisture and carbon content are expected to decline (p. 19). More frequent rain-on-snow events would increase erosion. Changes in precipitation, evaporation, and streamflow will affect vegetation growth. There is no discussion concerning the choice of revegetation species that could be more resilient to climate change. The SDEIS fails to take a hard look at the potential cumulative effects of climate change on revegetation success, soils and reclamation.</p>	RES	<p>Continued exploration in the Project area would be part of the SGP authorization. Therefore, it would be a direct effect of the Project rather than a cumulative effect. Other mining projects are considered in the cumulative effects analysis to the extent that they have been formerly proposed via submittal of a mine plan or otherwise publicized by their proponent. Additional mining would not be authorized via an SGP decision and would require further NEPA analysis and permitting.</p> <p>SDEIS Section 4.4.2.2 describes the effects of climate change on soils and vegetation. Vegetation species included in the reclamation plan are based on Forest Service requirements for revegetation and the revegetation goals associated with the Project.</p>
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	135	<p>8. The SDEIS lacks any discussion about financial assurance</p> <p>The SDEIS fails to include an analysis of the financial surety associated with reclamation and closure. The public is ultimately liable for this cost if the company cannot pay it, and it is liable for any difference between the amount established by the Forest Service for the financial assurance, and cost overruns of reclamation and closure that may occur. Cost estimates must be made conservatively in order to protect the public.</p> <p>In the 2019 Prefeasibility Analysis, the cost estimate for the financial surety was \$66.5 million. In the 2021 Feasibility Study that cost estimate increased to \$100 million. This cost calculation is not included in the EIS analysis, only in the feasibility analyses, but it has potential significant financial impact on</p>	RES	<p>Reclamation cost estimates and financial assurance decisions are conducted by the Forest Service in a separate administrative process outside the NEPA scope.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			taxpayers and the public. There is no technical justification for delaying the analysis of these calculations, since the calculations have already been done. The public deserves to be able to comment on these calculations as a part of the EIS.		
Idaho Regulatory Agencies	17718	15	Second paragraph - 1. What are the reclamation success criteria? 2. As written, it suggests that unconsolidated overburden will replace the growth media deficit, and will lead to reclamation success. This is not correct. 3. what are the "growth media deficit" amounts? How determined? Please reference other part of document.	RES	The text has been revised to replace "reclamation success criteria" with "reclamation suitability criteria". The reclamation suitability criteria are described in SDEIS Section 3.5.4.2. The comparison of available salvage soils versus growth media requirements is described in SDEIS Section 4.5.2.2 along with the utilization of unconsolidated overburden as growth media.
Amelia Weber	18155	4	Although Perpetua prefers to present the SGP as a 'restoration' project, it is a massive industrial mine that will leave the landscape unrecognizable and degraded for lifetimes to come through the creation of three open pits, the permanent storage of over 120 million tons of toxic mine tailings above previously undisturbed wetland habitat, and an expanded footprint that more than doubles the previous disturbance of the Stibnite mining district.	RES	No further response required. General in nature or position statement. It is acknowledged and understood that concerns regarding potential long-term environmental impacts, ecological integrity, and the well-being of potentially affected communities are valid and important to consider. During the decision-making process, the Forest Service will seek to identify the best possible balance between environmental protection, community needs, and sustainable forest management.
Brooke Dunnagan	18894	2	The reclamation efforts fail to meet the standards to repair the already extensive damage and plan to extend the range of damage from mining activities. I am asking that there be a more extensive and far reaching plan in order to reverse the damages already done at the site, and consequently downstream.	RES	The Project includes a Reclamation Closure Plan designed to return the site to post-mining land use. The Reclamation Closure Plan includes monitoring requirements to assess its effectiveness and trigger additional activity if reclamation standards are not met.
Benjamin Davenport, Executive Director, Idaho Mining Association	18777	4	The SGP demonstrates the opportunity that exists at old mine sites to recover critical minerals from legacy mine wastes while concurrently remediating a site impacted by past, unregulated mining practices. ⁷ As a prototype re-mining project, putting the SGP into production would be an important milestone in validating the concept that redeveloping and remediating old mine sites by re-mining and reprocessing legacy mine wastes represent a significant win for both the environment and the security of the Nation's critical minerals supply chains. The SGP also illustrates another important principle about the technical and economic challenges encountered at legacy mine sites. At many sites, including the Stibnite Mine, it may not be feasible to address all of the problematic legacy features in a mine plan that passes economic scrutiny. The substantial but partial restoration of the SGP proposed in the MMP illustrates the merits in pursuing partial cleanup measures that may ultimately lead to a more comprehensive restoration plan. For more than two decades, unrealistic and unachievable cleanup requirements have stymied policy and legislative debates about cleaning up abandoned mines. This stalemate has largely prevented both the private and public sectors from getting involved with legacy sites. The phased remediation scenario envisioned for the Stibnite Mine (see Section VII below) shows how stepwise site restoration measures represent a viable path for cleaning up old mines. The MMP initiates a path towards a site-wide, comprehensive cleanup that is achieved incrementally. The phased cleanup envisioned for the Stibnite Mine could potentially be applicable to other legacy mine sites.	RES	No further response required. General in nature or position statement.
Small, Nathan (Chairman, Fort Hall Business Council, Shoshone-Bannock Tribes)	18903	29	"Fluctuating economic conditions" should not be allowed to influence the life of the mine and the remediation/restoration activities. Perpetua should be committed/obligated to mine regardless of metals prices. Because pit mining is the primary ore source and tailings reprocessing is the secondary and last effort during the mine life, there is concern that tailings reprocessing will not be done as promised.	RES	Comment noted. Statement of position.
Michael Gibson (Trout Unlimited), Aaron Lieberman (Idaho Outfitters & Guides Association),	18871	27	A long standing mantra for Midas Gold/Perpetua has been to "Restore the Site." And while improvements are needed and necessary to repair historic mining impacts, the current SDEIS proposes to drastically increase the footprint of SGP with a project life span of 15-20 years. A full restoration of the site would leave behind a functioning hydrological system with groundwater connectivity. Studies show that groundwater upwelling and springs are an important attribute that helps anadromous fish key into spawning areas. The proposed reclamation of tributaries running through the site would entail building a	RES	The effects of restored stream channels on fish and fish habitat are described in Section 4.12.2.2. Assessment of the proposed restored conditions indicate that they would be suitable habitat based on a consideration of a number of factors.

Garret Visser (Idaho Wildlife Federation)			large lined trench over the top of tailings piles and then building a stream bed on top of this trench. Without connectivity to groundwater, this channel would become nothing more than a migration corridor if repopulated by trout and salmon.		
Deantha Skibinski, Executive Director, Alaska Miners Association	18899	7	<p>The SGP could become a template for how remining and reprocessing some legacy mine sites could recover critical minerals while concurrently remediating the impacts from past, unregulated mining practices.³ As a prototype remining/reprocessing project, putting the SGP into production would help validate the concept that redeveloping and remediating old mine sites by remining and reprocessing legacy mine wastes represents a significant win for both the environment and the security of the Nation's critical minerals supply chains.</p> <p>The SGP also illustrates the complexity of the technical and economic issues encountered at legacy mine sites. At the SGP, it is not economically feasible to include all of the problematic legacy features in a mine plan. This is the likely the case for many other legacy sites. Although the MMP includes substantial environmental restoration measures, some problematic legacy mine waste piles will not be remediated because they are located outside of the project boundary for the MMP.</p> <p>The substantial but partial restoration of the SGP proposed in the MMP illustrates three important principles with potential applications at other legacy sites:</p> <ol style="list-style-type: none"> 1. There is considerable merit in pursuing partial cleanup measures because some environmental restoration and improvement is better than no improvement; 2. A partial cleanup effort will get the ball rolling, which may stimulate and enable future more comprehensive cleanup measures; and 3. Addressing the range of environmental problems at a legacy site is complex and expensive. <p>Recognizing the urgency to eliminate selected mine waste piles that are outside of the MMP project boundary as ongoing sources of contaminated leachate, Perpetua entered into an Administrative Settlement and Order on Consent (ASAOC) with the Forest Service and the U.S. Environmental Protection Agency (EPA) in January 2021. As described in Section 1.3 of the SDEIS, the ASAOC is a phased plan designed to remediate the legacy features outside of the MMP project boundary. Perpetua initiated Phase 1 of the ASAOC in July 2022. In the future, Perpetua may be able to pursue the conceptual site restoration measures in Phases 2 and 3 of the ASAOC if and when Perpetua is producing gold and antimony from the Stibnite Mine.</p> <p>Under Phase I of the ASAOC, Perpetua is voluntarily addressing several areas identified as being time-critical by implementing restoration measures that will eliminate or reduce contaminant sources from these areas as quickly as possible. The Forest Service and the EPA are directing and supervising the ASAOC Phase I remediation activities, which will cost Perpetua \$12 million to complete. In addition to these direct, on-the-ground remediation costs, Perpetua provided the agencies with a \$7.5 million performance bond to guarantee this work.</p> <p>The ASAOC Phase I water quality improvements are anticipated to be completed by 2025 and include constructing stream diversion ditches to divert water away from legacy mine wastes that are contaminating area streams, removing approximately 325,000 tons of legacy development rock and tailings from locations in Meadow Creek and the East Fork that are currently adversely impacting water quality. Phase I also entails conducting baseline studies at five historic mine adits that are discharging mine drainage.</p> <p>Once the SGP has all of its operating permits and production is underway, Phases 2 and 3 of the ASAOC give Perpetua the option to remediate additional legacy mine features located outside the MMP project boundary. These phases will require additional baseline data and engineering studies. They will also require funding using a portion of the revenue derived from mine production.</p> <p>The sequential combination of the ASAOC Phase 1, the MMP, and the future ASAOC Phases 2 and 3 would ultimately achieve a comprehensive, site-wide restoration and cleanup of the Stibnite Mine site. It</p>	RES	No further response required. General in nature or position statement.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>is therefore imperative that the Forest Service, the U.S. Army Corps of Engineers, and the Idaho State regulatory agencies take immediate steps to set this remediation sequence in motion.</p> <p>The opportunity to achieve a complete cleanup of the Stibnite Mine site that Perpetua will subsidize is both unique and important. There may not be a similar opportunity in the future if the SGP is not built and operated. If this occurs, the lost opportunity costs would be enormous and the <i>status quo</i> environmental problems would adversely affect water quality, fish habitat, and ultimately people and communities for many years.</p>		
Deantha Skibinski, Executive Director, Alaska Miners Association	18899	8	<p>As described in Section 4.21.2.2 of the SDEIS, Perpetua is proposing to invest \$1.1 billion to construct the SGP. It does not appear that there are any other companies, communities, Tribes, conservation groups, or ENGOs that are ready to make this extraordinary investment to restore the Stibnite Mine site. It is thus obvious that the most certain path to cleaning up the Stibnite Mine site is for the Forest Service to publish a Final EIS and issue a Record of Decision (ROD) to approve the SGP as soon as possible.</p> <p>In evaluating the MMP, the Forest Service must carefully consider whether Congress is likely to appropriate the money necessary to remediate the Stibnite Mine site. In the past, the Forest Service and other federal agencies conducted some very limited remediation activities at the Stibnite Mine that consisted of partial remedies that were ineffective in stemming the flow of contaminants that continue to leach from this site.</p> <p>According to the November 8, 2021 letter from the Intermountain Region Regional Forester, Mary Farnsworth, to Idaho Congressmen Russ Fulcher and Mike Simpson, the Forest Service spent \$5.2 million to remediate the Stibnite mine site between 1992 and 2013. The whopping difference between \$5.2 million and \$1.1 billion suggests that it is highly unlikely that Congress will appropriate the funds necessary to enable the Forest Service to perform a meaningful cleanup at Stibnite. Without Perpetua's proposed investment of \$1.1 billion to redevelop and remediate this site, the Stibnite Mine area will continue to create serious environmental and ecological problems in the Payette and Boise National Forests for the foreseeable future.</p>	RES	No further response required. General in nature or position statement.
Joseph Pietri	19062	4	Will Perpetua be there through the end of restorations if profits decline?	RES	A reclamation closure bond would be utilized to complete restoration activities in the event that the Project operator is unable to complete the activities.
Karen Balch (North Fork Veterinary Service)	19228	10	<p>At the heart of Stibnite Gold Project's public media campaign is a promise to heal the historic mining blight of the Stibnite area that occurred most recently 50 years ago and beginning well over a century ago. That damage is adjacent to and intrudes on the largest Primitive Area in the lower 48 states – the joined Gospel-Hump Wilderness and Frank Church River of No Return Wilderness.</p> <p>Stibnite Gold Project's concept of restoration is to redisturb the current Stibnite mine site and excavate at the minimum an additional 800 acres of undisturbed wildlife and fish habitat. Two of three enormous mining pits projected to be left permanently on the landscape in perpetuity with single-layer liners that will eventually leak. All liners leak eventually due to the natural permeability of materials that also have defects. It is sobering that a 6.5 magnitude earthquake rolled through Idaho's Sawtooth mountain range on March 31 of this year. With an epicenter area 45 miles west of Challis, the center of this major earthquake was only a few dozen miles east of Stibnite. This was the second largest earthquake in Idaho history, and even 3 months later the area is experiencing a string of aftershocks, some registering as high as magnitude 4.8 (Idaho Statesman, June 25, 2020). 			<p>practices and financial assurance calculations so we can restore the site,” details specifying the actual particulars of bonding are not available.</p> <p>What is the monetary amount of the bond? What formula is used to calculate bonding and by whose calculations?</p> <p>What are the terms of the bond that the government is requiring for actual mining to begin?</p> <p>Historically, western United States is littered with abandoned mines – literally mined out with now-forgotten owners having declared bankruptcy to avoid additional costs. As an example, Montana’s Zortman and Landusky gold and silver mines, originally owned by the Canadian company Pegasus Gold Corp, went bankrupt and folded 20 years ago. As of March 2019, that abandoned mine continues to leave a legacy of water pollution and a cleanup bill nearing 100 million dollars that is expected to continue in perpetuity. Consider Colorado’s Summitville Mine that has cost American taxpayers over \$100 million in EPA cleanup and in 2021 Colorado state taxpayers were handed back a mine estimated to cost \$2 million annually in perpetuity or “forever” – it’s the mine that keeps on giving. In hindsight, how should a mining site that is permanently polluted, such as Summitville, be bonded so the public is not burdened by substantial costs forever?</p> <p>Given the past history of polluting exhausted gold mines abandoned in western United States, Stibnite Gold Project must provide robust financial evidence of fiscal bonding before permitting should even be allowed. And to appreciate the litany of devastation and death from cyanide gold mining see the list of gold mining disasters resulting from dam failure, cyanide leaking into the environment and inappropriate toxic waste discharge related to gold mining using gold cyanidation technique (https://en.wikipedia.org/wiki/List_of_gold_mining_disasters and the human loss of life).</p> <p>What assurances does the American Public have that Stibnite Gold Project (SGP) under one of Perpetua Resources Corp.’s subsidiaries will not simply declare bankruptcy or sell its mining interests to another company leaving a bigger colossal toxic mess. I don’t see that addressed.</p> <p>What assures that any mining company successors to SGP will be bound by any previous restoration agreements?</p> <p>What iron-clad incentives or agreements prevent SGP from simply abandoning its stated restoration plans after having gutted more pristine Idaho wilderness and profited from whatever gold was mined?</p>		
Olin Balch (North Fork Veterinary Service)	19234	6	<p>At the heart of Perpetua’s (previously Midas Gold’s) public campaign is a promise to heal the historic mining blight of the Stibnite area that occurred over decades and decades ago. That damage is adjacent to and intrudes on the largest Primitive Area in the lower 48 states – the joined Gospel-Hump Wilderness and Frank Church River of No Return Wilderness.</p> <p>However, Perpetua’s concept of restoration is to redisturb the current Stibnite mine site and excavate many, many more acres of previously undisturbed wildlife and fish habitat. As described the proposed SGP is a massive cyanide leach gold mining operation that doubles the area of land disturbance from 1,593 to 3,265 acres. This includes the excavation of three open pit mines. Two of three enormous mining pits are projected to be left on the landscape in perpetuity with liners that will eventually leak. All liners leak eventually. It is sobering that a 6.5 magnitude earthquake rolled through Idaho’s Sawtooth mountain range on March 31, 2020. With an epicenter area 45 miles west of Challis, the center of this major earthquake was only a few dozen miles east of Stibnite. This was the second largest earthquake in Idaho history, and even 3 months later the area is experiencing a string of aftershocks, some registering as high as magnitude 4.8 (Idaho Statesman, June 25, 2020). Earthworks’ 2013 U.S. Gold Mines Spills and Failures Report study that all 27 active U.S. gold mines had experienced at least one pipeline spill or other accidental release. Invariably the history of foreign and domestic companies who have mined US public lands for centuries is simply to leave without “cleaning up” once the ore is out of the ground and mining is no longer profitable.</p>		
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	26	"Each of these pits would also be backfilled with development rock to a certain degree which would bury certain portions of the open pits and their highwalls. " Please note the West End Pit would not be backfilled.	RES	The text has been revised to clarify that the West End pit would not be backfilled.
Ruth Lewinski	19378	11	<p>5.0 Allocated Cleanup Costs and Timeline</p> <p>For several decades, the Stibnite site has had different rehabilitation efforts. Thousands of tax-payer dollars have already been spent in attempts to 'clean' this site. Contaminants, particularly arsenic, in this region are above recommended environmental exposure thresholds CDC. While it is incredibly hopeful that Perpetua will clean this site in its efforts, it is not guaranteed. Under current Idaho policy, mining companies are able to claim credit for potential respiration costs. Due to the complexity and extensive history at this site, this is inappropriate. At least 50% of the potential respiration costs for this operation should be in capital bonds. In addition, the site (as previously proposed) should be an official CERCLA site with federal funding and efforts to have an adequate, appropriate, and long-lasting reclamation.</p>	RES	Comment noted. Statement of position.
David Chambers	17634-A	2	There are two very serious flaws with the technical analysis in the SDEIS. The first is the failure to include an analysis of the financial surety associated with reclamation and closure. The public is ultimately liable for this cost if the company cannot pay it, and it is liable for any difference between the amount eventually established by the Forest Service and the actual cost of reclamation and closure.	RES	Reclamation cost estimates and financial assurance decisions are conducted by the Forest Service in a separate administrative process outside the NEPA scope.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>In the 2019 Prefeasibility Study, the cost estimate for the financial surety was \$66.5 million. In the 2021 Feasibility Study that cost estimate increased to \$100 million. These cost calculations are not included in the EIS analysis, only in the feasibility analyses, but they have potential significant financial impact on taxpayers and the public. There is no technical justification for delaying the analysis of these calculations, since the mining alternative has been determined, and the financial assurance calculations have already been done. The public deserves to be able to comment on these calculations as a part of the EIS.</p>		
David Chambers	17634-A	9	<p>2.4.7.14 Closure and Reclamation Financial Assurance</p> <p>It is noted in this section, “Perpetua would be required to post financial assurance to ... provide adequate funding to allow the Forest Service to complete reclamation and post-closure operation, including continuation of any post-closure water treatment, maintenance activities, and necessary monitoring for as long as required to return the site to a stable and acceptable condition in the event Perpetua was unable to do so.”</p> <p>When mines are developed on their lands, a financial assurance is required by federal land managers and many state regulatory agencies. The financial assurance is to cover the cost of reclaiming the disturbed surfaces of the mine, and to pay for all post-closure requirements. In this case, a significant part of the financial assurance will be for the cost of water treatment.</p> <p>It is also important to note that the financial assurance does not cover the cost of a potential mine accident. The financial assurance only covers planned closure.</p> <p>The financial assurance requirement is important for several reasons.</p> <p>First, there have been numerous instances in virtually every state of mining companies going bankrupt and not having the financial resources to complete their closure obligations– for example, the Illinois Creek mine in Alaska, and the Zortman-Landusky mine in Montana. In these instances, the government regulatory agencies did not require enough financial assurance to cover the actual costs of mine closure.</p> <p>In British Columbia, it is estimated that the Province holds over \$1 billion less than the full value for financial assurance required to reclaim BC mines. If the mining company cannot clean up and close the mine, then the public becomes liable either for the cost of cleanup, or for the environmental consequences of the damaged minesite.</p> <p>There is significant political pressure to keep the costs of these financial assurances as low as possible in order to enhance the economic viability of the mine. In the past, this has led to significant underestimations of the amount of financial assurance required to close a mine after a bankruptcy.</p> <p>Alaska, Montana, Nevada, South Dakota, and other states have been victims of this problem. In each instance, taxpayer dollars were required to augment inadequate financial sureties.</p> <p>Second, the amount of money required to close the mine and to perform post-closure water treatment can be enormous. The present financial assurance for closure of the Red Dog mine in Alaska is \$563 million, most of which is related to water treatment in perpetuity. At closure, the Red Dog mine is projecting to treat approximately 1.8 billion gallon/year, which drives the majority of the financial assurance requirement. Perpetual water treatment at Stibnite would add hundreds of millions of dollars to the closure cost, which must be covered by the financial assurance.</p> <p>How the agency responsible for calculating the financial assurance to insure that public will not be saddled with these costs is an important issue that is being avoided in the EIS. Public disclosure, and an opportunity to review the cost calculations, is not only appropriate, but the potential financial and/or environmental impact on the public is also significant.</p> <p>The National Environmental Policy Act requires federal agencies to undertake a pre-action analysis in the form of an Environmental Impact Statement (EIS) of potential environmental impacts for “major</p>	RES	<p>Reclamation cost estimates and financial assurance decisions are conducted by the Forest Service in a separate administrative process outside the NEPA scope.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>Federal actions” that may “significantly affect” the quality of the human environment. 42 U.S.C. § 4332(2)(C).</p> <p>The Code of Federal Regulations, Title 40: Protection of Environment defines “human environment” as: §1508.14 Human environment.</p> <p>Human environment shall be interpreted comprehensively to include the natural and physical environment and the relationship of people with that environment. (See the definition of “effects” (§1508.8).) This means that economic or social effects are not intended by themselves to require preparation of an environmental impact statement. When an environmental impact statement is prepared and economic or social and natural or physical environmental effects are interrelated, then the environmental impact statement will discuss all of these effects on the human environment. (emphasis in original) If a financial guarantee is required to protect environmental values, like clean water and fish, then 40 CFR1508.14 clearly suggests that the significant financial assurance required by agency regulations should be evaluated in an EIS. When a federal agency intentionally decides to ignore analyzing the requirement for a financial assurance to protect the environment, the message it clearly sends is that it is not confident in its ability to defend its financial assurance calculations to the public. Deferring the analysis of the financial assurance requirement until later in the permitting process expedites the permitting process, as well as make it more difficult, if not impossible, for the public to review and comment on the adequacy of the financial assurance requirement.</p> <p>Reclamation and Closure costs are not only a significant factor for calculating the capital costs of a mine, but are also a potential major liability to the public if they are not properly calculated and managed. This means Reclamation and Closure costs could have a major potential impact on the economic environment of both the community hosting the mine, and the taxpayers who would be liable to pay the costs of reclamation and closure if the mining company becomes financially insolvent. Under the NEPA definition of “significant environmental impact”, the potential impacts of an inadequately calculated financial assurance for the reclamation and closure of this mining project could have significant economic, social, and environmental impacts. The financial assurance should be analyzed as a part of this SDEIS.</p> <p>In the SDEIS, it is important to disclose and analyze the assumptions that will be made in establishing the financial assurance the amount of post-closure financial assurance needed to protect the public if water treatment is required beyond Mine Year 40. At a minimum, tens of millions of dollars are at issue.</p> <p>However, in the SDEIS it is noted: “Calculation of the initial bond amount would be completed following the Record of Decision (ROD) when enough information is available to adequately and accurately perform the calculation.” (SDEIS 2022).</p> <p>The information available at this stage of the mine design, and for the SDEIS analysis, is more than sufficient to analyze the Reclamation and Closure costs. In fact, those calculations have already been made in the Feasibility Study (M3 2021). The Forest Service has decided not to include them in the SDEIS. By doing so, the Forest Service is playing a classic game of “hide the ball”.</p> <p>In its 2021 Feasibility Study, M3 notes: “Anticipated costs for closure and reclamation of the Stibnite Gold Project were developed utilizing the Standardized Reclamation Cost Estimator (SRCE) model currently used and developed in Nevada for mining specific projects, supplemented by site-specific costs and quantity estimates from the FS designs. This model has been utilized for mining projects on public and private land in Nevada and other western states for many years and is publicly available online through the Nevada Division of Environmental Protection.” (M3 2021)</p> <p>As M3 notes, the Nevada Standardized Reclamation Cost Estimator is probably the most widely used spreadsheet model used to calculate the costs of reclamation and closure. I have used this model, and it contains of all of the sections necessary to calculate cost estimates for reclamation, closure, and postclosure activities, including perpetual water treatment, and the additional costs that would be incurred should a regulator be forced to conduct reclamation and closure activities if the mining company were to become financially insolvent.</p>		

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>M3 included the calculation of these costs in the Prefeasibility Study (2019) because they constitute a significant line item in the capital requirements for the proposed project. In its 2019 Prefeasibility Study, M3 calculated this cost at \$66.5 million (M3 2019). This estimate included the cost of the financial surety/bond from a financial institution.</p> <p>For the 2021 Feasibility Study, as noted above, M3 stated the reclamation and closure cost calculation would be finalized after the Forest Service issued a record of decision. However, M3 did calculate a reclamation and closure cost, but listed it only as cost per ounce of gold produced. That cost was \$24/oz produced. Using \$24/oz produced, and the total life of mine production is 4,819,000 ounces of gold, I can calculate the total reclamation and closure cost of \$100 million.³ This is almost double the 2019 cost estimate of \$66.5 million (M3 2019). The public is ultimately liable for this cost if the company cannot pay it, and it is liable for any difference between this amount and the actual cost of reclamation and closure, if the actual cost should be greater than the \$100 million.</p> <p>Why is there such a significant difference between the 2019 cost of \$66.5 million and the 2021 cost of \$100 million? Did the cost calculation assume water treatment for 40 years, or for treatment in perpetuity, which would be protective of the taxpayers? What assumptions were made for the Indirect Costs associated with a government agency assuming the responsibility for reclamation and closure? Indirect Costs typically vary between 25% and 45% of the direct reclamation and closure costs. What assumptions were used for the present value calculations to pay for post-closure water treatment, and for monitoring and maintenance? Who will manage the post-closure fund? What rate of return for the investment was assumed?</p> <p>These are all questions that can be answered now, and those answers will not change between the present time and the issuance of the record of decision and permits for the mine. The financial assurance calculation is an issue that can, and should, be discussed now. The public deserves to know these answers, and deserves to be able to comment on them, as a part of the EIS. There is no reason to hide the ball.</p>		
Samuel Penney (Chairman)	19396	46	<p>2.4.7 Closure and Reclamation</p> <p>The SDEIS states, "[c]losure and reclamation activities would be intended to achieve post-mining land uses of wildlife and fisheries habitat and dispersed recreation at the SGP."⁹³ The SDEIS needs to expressly identify, fully evaluate and disclose impacts to the Tribe's 1855 Treaty-reserved rights and access to Tribal cultural resources as post-mining land uses. Vague references to "wildlife and fisheries habitat" or "dispersed recreation" are inadequate and do not address the unique treaty rights and other interests the Tribe has at the mine site and within the affected area.</p>	RES	SDEIS Section 4.24.2.2 describes potential effects on tribal treaty rights and interests.
Samuel Penney (Chairman)	19396	60	<p>According to SDEIS Section 2.4.5.13 "Mine Site Borrow Sources various types of earth and rock material would be used from borrow sources for construction, maintenance, closure and reclamation activities. Most of these materials can be sourced at the mine site from existing development rock dumps, legacy spent heap leach ore in the spent ore disposal area and legacy heap leach facilities, and from development rock removed as part of proposed surface mining and underground exploration activities. These materials would be subject to physical and chemical testing to determine suitability for use." This description does not identify the actual quantities of borrow materials for reclamation and closure that would be required. According to SDEIS Section 4.5.2.2 Reclamation Cover Materials, "[a] total of approximately 1,658,075 bank cubic yards ("BCY") of suitable soils (Growth Media ("GM") and seed bank material ("SBM")) would need to be salvaged from the SGP for reclamation. A total of approximately 860,373 BCY of GM, chipped wood blend, and SBM are available for salvage at the SGP. The GM deficit is thus estimated at approximately 797,702 BCY."¹⁰⁵ "Options being considered by Perpetua for developing additional GM for the SGP include: utilizing materials from off-site borrow areas and supplementing additional salvage of GM through composting." The SDEIS does appear to recognize the challenges associated with reclamation materials in SDEIS Section 4.5.2.2 Reclamation Cover Materials despite summarizing that the overall relatively poor quality of the soils at the mine site (outside of valley bottom soils), the long-term stockpiling of growth media/seed bank materials, and the high background concentrations of metals in soils would affect the quality and suitability of available</p>	RES	The Reclamation Closure Plan is summarized in the EIS document. Reclamation includes performance monitoring to assess the effectiveness of revegetation and allows for modifications in the event that reclamation and revegetation goals are not achieved.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			reclamation cover materials. These challenges, coupled with the harsh winter climate (short growing season) and generally steep slopes of the area, would compound to present difficulties in growing and/or maintaining persistent vegetation cover over reclaimed areas. This is consistent with the mixed vegetative cover success of nearby reclaimed mining areas and the previous efforts by Perpetua and others at the mine site to establish self-sustaining cover on previously mined lands that have had some limited success. However, the suggestion in the DEIS, that adding a marginal amount of organic material as suggested, will somehow provide the answer is unsupported. Particularly given the expectations of infiltration reduction that have been attributed to the reclamation covers, the matter of borrow materials suitability and availability is of more significant concern and challenge than suggested by the SDEIS.		
Samuel Penney (Chairman)	19396	61	There is a well-established history of inadequate borrow material characterization leading to environmental impacts as a result of using unsuitable material for foundations and other needs. For this reason, the borrow sources should be identified and physically and chemically characterized and analyzed in the SDEIS rather than this subject being deferred to a later time. In addition, it is important to establish whether adequate quantities of materials for reclamation and closure respective of each Alternative analyzed in the SDEIS are actually available as otherwise additional borrow sources, not addressed in the SDEIS, could be required. Finally, the overall approach to reclamation cover materials should be further assessed including the practicality of construction of cover layers in 6 – 12 inch thicknesses, particularly where an engineered cover including a geomembrane liner is concerned, combined with revegetation challenges, and expectations that performance must be ensured over a very long time in the future.	RES	Chapter 2 describes the number, location, and criteria for proposed borrow sources. Installations of geosynthetic liners and soil covers are achievable by existing technologies and practices that are subject to technical specifications and quality controls.
Samuel Penney (Chairman)	19396	65	<p>The SDEIS describes the process of TSF closure in Section 2.4.7.6 TSF and TSF Buttress as follows, “After tailings consolidate sufficiently to use heavy equipment on top of the tailings, starting approximately 3 to 5 years after the end of deposition, Perpetua would begin with placement of cover material, then construct wetlands and restore Meadow Creek and its tributaries within appropriately sized lined floodplain corridors, place growth media, and revegetate the area.”</p> <p>Experience has shown that the consolidation of tailings is highly variable and site specific, and that final reclamation can require significant additional time than is inferred, since it is not described in detail. The Mount Polley Independent Expert Review Panel identified three principles for best available technology for existing TSFs as: no surface water; unsaturated conditions; and, achieve dilatant conditions by compaction. The Canadian Dam Association describes TSF closure in four phases related to the management of risk of TSF’s depending on their state of closure.</p> <ul style="list-style-type: none"> • The SDEIS should include an RCP that identifies, in reasonable detail, what stage of TSF closure is expected to be achieved, how closure is to be achieved, and when in accordance with Canadian Dam Association recommendations. • The SDEIS should also identify stable landform closure as an alternative for the TSF if it is not clear that the proposed action would result in that condition being achieved within a reasonable time-frame. <p>The SDEIS description in Section 2.4.7.12 Contouring, Grading, Growth Medium Placement, and Seeding is potentially the most minimal description of land reclamation activities ever provided in the history of NEPA documentation dealing with hardrock mines. The SDEIS only references an RCP in the context of not describing a reclamation seed mix and rates. No information is provided specific to the reclamation schedule.</p> <p>The SDEIS should have more completely described the RCPs and provided important details such as the proposed cover design. An additional level of detail for the plans is necessary to conform with Forest Service regulations and guidance¹⁰⁹ which is the subject of the SDEIS, and should not be delayed or deferred to the Idaho permitting processes. The applicant should have submitted its application to the Idaho agencies and advanced that process concurrently with the SDEIS, but if they did not then the Forest Service should have required it during the technical completeness review process prior to initiation of the NEPA process. The SDEIS should be supplemented to include this information, including as it pertains to the effects-analysis, and the SDEIS re-issued for public review.</p>	RES	<p>Section 2.4.7 summarizes the proposed TSF reclamation as detailed in the Reclamation Closure Plan. This summary describes the expected timing for the various closure activities which are generally related to management of the residual process solutions contained by the impoundment at the time of closure.</p> <p>Geotechnical analyses of the operational, closure, and post-closure TSF, embankment, and buttress conclude that the reclaimed TSF would be a stable facility.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Samuel Penney (Chairman)	19396	69	<p>Potential additional care and maintenance measures that should be considered by the Forest Service to minimize long-term liability of reclamation uncertainties include long-term settlement of the waste rock piles and TSF, functionality of stormwater drainage channels and sediment ponds, stability of the TSF and other constructed river channels, and effects from climate change.</p> <p>If a long-term trust fund will be established for the proposed project, the appropriate level of funding, types of financial instruments, and mechanics of the fund are critical to ensure that sufficient funds will be available when needed. In addition to the projected long-term engineering, maintenance, and monitoring costs of each activity, the SDEIS should discuss the financial assumptions used to estimate the funding levels, projected trust fund growth rate, and mechanics of the trust fund. The fund mechanics include: (a) requirements for timing of payments into the trust fund; (b) how the responsible agency ensures that the trust fund is bankruptcy remote; (c) acceptable financial instruments; (d) legal structure of the trust fund for tax purposes; (e) who will pay the taxes on trust fund earnings and trust fees and expenses; (f) how will taxes and fees be paid on the trust if the mining company goes out of business; (g) who will make investment decisions if the operator is no longer viable; (h) if the federal government controls the investment decisions, what legal and ethical issues arise from the responsible agency controlling investment decisions about investments in private companies, voting stock and similar issues if the trust owns stock; (i) the identity of the trust fund beneficiaries; and (j) the identity and corporate structure of the operator with responsibility and liability for financial assurance at this site.</p> <p>The Project includes measures and controls that would require long-term post-closure operations and maintenance to protect water quality. The need for long-term post-closure operations and maintenance, facilities replacement, and monitoring should be acknowledged in the SDEIS. The SDEIS should contain adequate details regarding financial assurance commitments (e.g., for reclamation and long-term operations and maintenance) as well as meaningful assurances that a proper financial instrument will be established to ensure that adequate funds are available as long as they may be needed for this purpose.</p>	RES	<p>SDEIS Section 4.2.2.2 describes the geotechnical risks associated with the Project facilities and the design features, requirements, and other measures that would be implemented to minimize these risks.</p> <p>The Final EIS includes information regarding a long-term trust for maintaining restoration and reclamation.</p>
Samuel Penney (Chairman)	19396	81	<p>The SDEIS states that total arsenic was identified as having the greatest potential for phytotoxicity in plants at the site, but does not provide any further information. The SDEIS needs to describe the affected environment which includes research and restoration efforts to date regarding soils and vegetation. It needs to include findings from the soil survey generated by Tetra Tech, including information from the root zone analysis, Hecla reclamation efforts, and evaluations of vegetated soil within and adjacent to the Project area.</p>	RES	<p>The Reclamation Closure Plan and associated soil surveys describe the Project areas current state with regard to soil quality, vegetation, and reclamation revegetation. These results are summarized in Section 3.5.</p>
Samuel Penney (Chairman)	19396	182	<p>The SDEIS discloses that the best salvaged materials will be reserved for wetland restoration while poor quality mediums will be used for upland reclamation. This is unacceptable considering (again) that soil quality will be further compromised from long-term storage in deep stockpiles (piles 200' tall stored for 1 to 42 years). Sacrificing uplands for the sake of wetlands does not comply with NFMA and Forest Plan direction. Lands should be treated equally.</p>	RES	<p>Comment noted. Statement of position.</p>
Samuel Penney (Chairman)	19396	184	<p>The Tribe has little faith that the Project area will be reclaimed to a condition that is better than existing conditions given the proposed impacts to soil quality, delays between initial disturbance and final reclamation (> 16y), and that past reclamation efforts have not been successful. The amount of suitable soil available as growth media is suspect given that soil horizons and suitability vary across the Project area. The Tribe is not optimistic that reclamation efforts will sustain Tribal resources in perpetuity. Because there are inadequate resources to reclaim all lands disturbed by the Project to a condition commensurate with pre-mining conditions and that the purpose and need of the Project does not align with NFMA and Forest Plan management direction (i.e., the Project will not move the landscape toward desired conditions, will create adverse impacts to Treaty resources and exercise of Treaty rights, and jeopardizes the trust responsibility that the Forest has to the Tribe), the Forest needs to reject the Project.</p>	RES	<p>Comment noted. Statement of position.</p>
Samuel Penney (Chairman)	19396	201	<p>The SDEIS should address the expected efficiency and longevity with respect to maintenance and replacement of the underdrain system given it will be required to continue to operate as per design in perpetuity, and address/include mitigation in the event of the failure of the underdrain system.</p>	RES	<p>The TSF is predicted to dewater over a period of 40 years. Leak detection systems would be able to detect leaks during the period when saturated conditions are present in the tailings which is not expected to persist in perpetuity.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			The SDEIS should also outline a plan for detecting leaks in all geosynthetic cover systems (both the bottom and top covers) in perpetuity.		The TSF underdrains would collect spring and seep flows beneath the TSF impoundment and embankment. Because they are separated from the TSF materials by a geosynthetic liner system, these flows would be handled as non-contact water and are expected to exhibit water chemistry consistent with existing conditions. In the event of an underdrain system failure, these waters would remain in the subsurface as groundwater flow.
Samuel Penney (Chairman)	19396	202	The SDEIS does not address methods to ensure that the geosynthetic bentonite clay cover at all covered sites will remain properly hydrated to prevent cracking and subsequent leaking. This is especially relevant to the covering of tailings to prevent further leakage. Studies using geosynthetic covers incorporating a layer of bentonite encased between nonwoven and woven geotextiles, laminated with a polyethylene geofilm and 769 mm (~30 inches) of sandy planting medium planted with perennial grasses did not prevent cracking of the laminated bentonite, subsequently increasing annual seepage rates. These findings suggested that plant roots were likely the cause of substrate dehydration and subsequent bentonite cracking. Based on these findings, the proposed 12 inches of planting medium above the geosynthetic covers is therefore insufficient to prevent drying of the bentonite layer after being planted leading to perpetual seepage while increasing annual seepage rates.	RES	The Reclamation Closure Plan proposes the use of geosynthetic liners installed over prepared subgrades. The current proposal does not include the use of bentonite clays as part of the liner installations.
Samuel Penney (Chairman)	19396	241	According to the RCP, post-mine conditions will not be conducive to whitebark pine growth, therefore it will not be included in the seed or planting mixes. This is unacceptable.	RES	Comment noted. Statement of position.
Samuel Penney (Chairman)	19396	299	The effectiveness of a post-mining, reestablished EFSFSR channel across the Yellow Pine pit is questionable due to a lack of groundwater interactions from the lined channel, riparian cover which will take decades to establish and provide shade, and an unknown timeframe for when mining will cease due to ongoing exploration.	RES	SDEIS Section 4.9.2.4 acknowledges uncertainties regarding the establishment and performance of the restored stream channels. Section 4.9.3 includes mitigation measures to address those uncertainties regarding the timing and effectiveness of the stream restoration.
Samuel Penney (Chairman)	19396	300	Touting adaptive management is only as good as the "clearly identified outcomes" which are difficult to predict in such a large and complex mining operation as the proposed Stibnite Gold mine. The timeframe of the project is directly tied to the ongoing exploration which is designed to prolong the mining. Although the stream "enhancements" and restoration, such as restoring passage at the box culvert are touted as positive habitat improvements, the timeframe for completion are uncertain if continued exploration extends the mine life. Efforts such as riparian restoration may take decades to become established due to a harsh growing environment. Some restored stream segments may not ever become suitable aquatic life habitat due to a number of factors.	RES	SDEIS Section 4.9.2.4 acknowledges uncertainties regarding the establishment and performance of the restored stream channel. Section 4.9.3 includes mitigation measures to address those uncertainties regarding the timing and effectiveness of the stream restoration.
Samuel Penney (Chairman)	19396	430	Financial Assurance Which agency will be taking charge of the financial assurance, the Forest Service or the Idaho Department of Lands? The Federal government will not accept corporate guarantee bonding. The development of financial assurance at this proposed mine site should include a transparent review process with consistent reporting listing how each variable adds up to the final amount.	RES	Reclamation cost estimates and financial assurance decisions are conducted by the Forest Service in a separate administrative process outside the NEPA scope. The Forest Service would hold the financial assurance for activities covered under its approval of the mine plan and its associated reclamation plan. State regulatory agencies such as the IDL hold the financial assurance for activities authorized under their permitting purview.
R. Skipper Brandt, Ted Linsely, Denis Duman		2	In communities throughout our country, we regularly see the scars left by historical mining on our landscape. It is important to us, and our local citizens, that before this project is approved it must first meet the strictest financial assurance requirements. We must be assured that the funding required to provide the required reclamation of Stibnite is set aside and protected through widely accepted financial tools rather than corporate guarantees.	RES	Reclamation cost estimates and financial assurance decisions are conducted by the Forest Service in a separate administrative process outside the NEPA scope. The Forest Service does not accept Corporate guarantees as a form of financial surety for reclamation costs.
Samuel Cousins		27	21. Monitoring Responsibility. The SEIS and FEIS must make it clear exactly what entities are responsible for each monitoring throughout the entire 35 year term of the project. In no cases should the Forest Service take on, or assign monitoring responsibility away from, Perpetua (or its successors) to the Forest Service or other Federal, State, or local agencies of individuals.	RES	Monitoring responsibilities will be assigned via the Forest Service decision on the Project that will specify that the permittee has the mining responsibility. Any modification of monitoring responsibilities would be subject to a permit modification approved by the Forest Service.
Samuel Cousins		28	22. Restoration Without Mining. Perpetua in its Proposed Project seems to believe "the "village must be destroyed to save it later." This assumption is false. Instead of the proposed action of superimposing a major new mining complex on top of a badly degraded but slowly recovering landscape, the better and	RES	Comment noted. Statement of position.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			more logical alternative is to continue the present recovery underway and increase restoration actions to help nature take its course.		
Alan Prouty		3	<p>This Project Provides a Model on Addressing Abandoned Mine Sites</p> <p>It is well recognized that historical mining that occurred in the United States before the advancement of environmental law and environmental protection technology, has resulted in a large number of abandoned mine sites that release hazardous substances into the environment. The Stibnite site, as mentioned above, was mined before such laws and technologies existed, and is a legacy mine site that releases contaminants into the environment. The United States Congress has wrestled for a number of years with how to address such mine sites. One concept has been called a "Good Samaritan" approach: i.e., develop a legal mechanism for an entity/organization to address the contaminants/ environmental damage from such legacy mine sites. This project will accomplish such a purpose and provide an example of how a historical mining area can be "re-mined" to recover metals valuable (and critical) to the U.S. economy while addressing and resolving historical impacts from a legacy mine site. Such a "demonstration" project is invaluable to demonstrate a viable way to address (with many benefits) this very important natural resource issue.</p>	RES	Comment noted. Statement of position.
John Rygh		6	Climate change presents yet another challenge to successful reestablishment of vegetation and is only addressed in passing in the Climate Change Specialist Report (U.S. Forest Service {Forest Service}, 2022b). Soil moisture and carbon content are expected to decline (p. 19). More frequent rain-on-snow events would increase erosion. Changes in precipitation, evaporation, and streamflow will affect vegetation growth. There is no discussion concerning the choice of revegetation species that could be more resilient to climate change.	RES	SDEIS Section 4.4.2.2 describes the effects of climate change on soils and vegetation. Vegetation species included in the reclamation plan are based on Forest Service requirements for revegetation and the revegetation goals associated with the Project.
John Rygh		8	Given the numerous adverse factors and uncertainties noted above, the long-term success of the postmining reclamation of the site is very much in doubt, with the final outcome conceivably being essentially an ecological sacrifice zone.	RES	SDEIS Section 4.9.2.4 acknowledges uncertainties regarding the establishment and performance of the restored stream channels. Section 4.9.3 includes mitigation measures to address those uncertainties regarding the timing and effectiveness of the stream restoration.
John Rygh		9	Then there's reclamation bonding. The Forest Service needs to explicitly state that all financial assurance instruments for the bond meet federal guidelines that preclude the use of corporate guarantees. Perpetua successfully lobbied to get the State of Idaho to accept corporate guarantees which are expressly forbidden by the Forest Service after the spate of huge defaults in the 1990s. If the State of Idaho ends up setting the bond for the private parcels at Stibnite, the Forest Service needs to increase their bond to account for the potential for contaminated surface water and/or groundwater to travel onto Forest land in the event that Perpetua defaults on their State bond.	RES	<p>Reclamation cost estimates and financial assurance decisions are conducted by the Forest Service in a separate administrative process outside the NEPA scope.</p> <p>The Forest Service does not accept Corporate guarantees as a form of financial surety for reclamation costs.</p> <p>The Forest Service financial assurance decision would not include amounts conceived as deficiencies in bonds determined by other regulatory agencies.</p>
Doug Stowers		3	As multiple generational residents of central Idaho, my family has witnessed firsthand the suffrage caused by government officials that implemented broad sweeping environmental protection measures that were closed minded and failed to factor the economic impact of the people that live within. These measures decimated our small towns to a point where poverty was prevalent and the pursuit of the American dream often meant that the application for food stamps was successfully submitted. Today, although we understand that the measures taken were vitally important to the preservation of Central Idaho's landscape and wildlife, we realize that the "human element" can now be factored in while devising a plan for environmental protection because of the scientific discovery of ulterior methods that previously were nonexistent. Perpetua Resources has designed plans to overcome multiple environmental issues that have gone by the wayside for decades and many would be substantially beneficial to central Idaho's residents and its wildlife. One example is a plan to construct a fish bypass tunnel that would aid anadromous salmon and steelhead in returning to historic spawning grounds that have not been accessible to these creatures in over 80 years! Another example is a detailed plan to reprocess old mine tailings that currently contain hazardous amounts of mercury and other destructive elements, extracting amounts that would stop harming the areas fish, wildlife and residents.	RES	Comment noted. Statement of position.

Alternatives

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Elizabeth Barnes	6652	40	Why is underground mining not considered as an alternative? When an open pit mine has never been able to operate without severe environmental contamination in the history of the United States.	ALT	The reasons why underground mining was not considered as a reasonable alternative to the proposed open pit mining method is discussed in Section 2.6.1.1 of the SDEIS.
Elizabeth Barnes	6652	44	The alternative action option of "no mine" is not seriously considered in the EIS despite its clear benefits to human health, water quality, endangered species, aquatic food chains, and fish. Why is the EIS written without due attention to the no action alternative?	ALT	The No Action Alternative was evaluated in Section 2.3 of the SDEIS and in each of the resource sections of Chapter 4.
Bowen, Mike (Executive Director, New Mexico Mining Association)	16872	5	<p>The unacceptability of the No Action Alternative is equally clear. It is impossible to imagine any viable reason for the Forest Service to select the No Action Alternative as the Agency Preferred Alternative in the FEIS. Selecting the No Action Alternative would preserve and prolong the environmentally degraded status quo and forego this unique opportunity to use private-sector resources to clean up the Stibnite mine site.</p> <p>In our October 2020 comments on the DEIS, NMMA stated that the DEIS did not adequately describe the policy implications of the No Action Alternative. Unfortunately, this continues to be the case for the SDEIS, because the SDEIS does not fully describe the numerous environmental restoration measures that would not be built and the environmental improvements that would not materialize under the No Action Alternative. NMMA suggests the FEIS should include a more complete discussion of the adverse impacts to the environment and to national defense and military preparedness under the No Action Alternative. This discussion should disclose the enormous lost opportunity costs associated with the No Action Alternative.</p>	ALT	Consideration of a No Action Alternative is a requirement of all EISs. Each resource section of Chapter 4 of the EIS has a section discussing the effects of implementing the No Action Alternative on the subject resource. The differences between the socio-economic effects of the 2021 MMP vs. the No Action Alternative are described in Sections 4.21.2.1 and 4.21.2.2 of the SDEIS.
von Lindern, Ian (Founder, Terragraphics International Foundation)	17436	7	The Preferred Alternative is New and Improperly Substituted in the SDEIS: The Forest Service has failed to evaluate appropriate Alternatives in both the DEIS and SDEIS. As noted, the Forest Service has abused the NEPA process, by extending extraordinary and inappropriate deference to Midas and Perpetua, and allowing new Alternatives to be substituted during the EIS period without Public Review. The SDEIS summarizes: "This SDEIS was prepared in response to a modified Plan of Restoration and Operations (Plan) for the SGP. The Forest Service received the original SGP Plan in 2016, (Midas Gold Idaho, Inc. [Midas Gold] 2016a) for review and approval in accordance with regulations at 36 Code of Federal Regulations (CFR) 228 Subpart A. A revised Plan, also known as MoDPRO(1), was submitted to the Forest Service in 2019 (Brown and Caldwell 2019a). A further modified Plan, also known as ModPRO2(2), was initially submitted in December 2020 with a revised submittal in October of 2021 (Perpetua 2021a)."	ALT	<p>Section 1.9 of the SDEIS states that the comments received on the 2020 DEIS were reviewed and considered as additional scoping input for the SDEIS preparation. These comments were analyzed in a content analysis process to develop public concern statements. Perpetua also reviewed the comments received on the 2020 DEIS and sought to respond to many of these comments by revising and resubmitting their Plan of Operations. This process produced the Modified Plan of Operations (ModPro2) submitted in October 2021, which then became the 2021 MMP which constituted a revised Proposed Action for Forest Service review. Sections 1 and 2 of the ModPro2 document explain how the changes in the modified plan of operations is partly in response to comments received on the 2020 DEIS. Appendix A of the ModPro2 document shows the comparison of the action alternatives reviewed in the 2020 DEIS and the ModPro2 plan. Because the 2021 MMP contained changes to the Proposed Action that are relevant to environmental concerns, the Forest Service decided to prepare a SDEIS. Also, based on comments received on the 2020 DEIS and the effects of the 2021 MMP, the Forest Service revised the action alternatives considered in the SDEIS. A major change in the format of the SDEIS and the 2020 DEIS was that technical supporting information was moved from the EIS to supporting specialist reports. The authors of these reports reviewed the public concern statements derived from the 2020 DEIS comments which advised the specialist report authors regarding content of those reports to be responsive to what was learned from the 2020 DEIS comments. Per 40 CFR § 1503.4(a) the Final EIS responds to individual comments or groups of comments. The Final EIS contains responses to both the comments received on the DEIS and SDEIS.</p> <p>The commenter submitted quantitative re-evaluation of the chemical characterization data in the 2020 DEIS to prepare elemental material balances for the different ore and waste materials of the operations. However, the elemental material balances are not solely indicative of potential environmental effects or how these effects compare to existing regulatory limits and guidance. These elemental material balances are not typically used in NEPA analyses of proposed mining operations. The impact analyses included in the SDEIS do utilize typically acceptable data and methods to predict chemical impacts to environmental media and then compares these projected impacts to existing regulatory requirements and guidance.</p>

von Lindern, Ian (Founder, Terragraphics International Foundation)	17436	8	<p>The evolution of these documents was also at issue in the IDEQ Permit to Construct (PTC). SGP has pursued and, although under Administrative Appeal, obtained a PTC for a facility capable of processing 180,000 tons/day of ore from the IDEQ. The initial PTC proposed by IDEQ did not address 99% of arsenic emissions from the proposed facility. Yielding to public scrutiny, IDEQ relented and required these emissions to be addressed in the PTC. The subsequent PTC application was also found to be insufficient. IDEQ accepted Perpetua's contention that there was no reasonably available control technology (RACT) addressing arsenic emissions from the proposed facility that could meet airborne carcinogenic risk criteria. IDEQ granted Perpetua TRACT relief from the carcinogenic criteria, allowing a ten-fold increase in cancer risk, and imposed production limits of 75% of capacity on operations. PTC Appellants argue these limitations are ineffective, as arsenic emissions and ambient concentrations are grossly under-predicted, the limits are not enforceable, and no monitoring is required to ensure compliance. (IDEQ 2022a,b).</p> <p>The Forest Service should recognize the initial configurations rejected by IDEQ are the Alternatives presented in the DEIS, and the alleged refinements are new Alternatives developed to comply with IDEQ requirements. The Forest Service SEIS Preferred Alternative (as noted in the SGP 2021 Modified Mine Plan (MMP) Alternatives Report (Forest Service 2022a)), is actually the 2021 MMP that includes the limits imposed by IDEQ. As a result, the Forest Service has selected a Preferred Alternative that differs significantly from the original scoping and the DEIS Alternatives.</p>	ALT	Most of this comment addresses the IDEQ permitting actions not the SDEIS. The SDEIS responds to a different Proposed Action (40 CFR. § 1502.9(c)(1)) than was considered for the DEIS, and also public input received on the DEIS, thus the action alternatives for the SDEIS can be different than those considered in the DEIS (40 CFR. § 1503.4 allows "[m]odifying alternatives including the proposed action" and "[d]eveloping and evaluating alternatives not previously given serious consideration by the agency"). The air impact analysis in the SDEIS is contained in Section 4.3 and is based on the description of the operations contained in the 2021 MMP submitted to the Forest Service for its permitting process. The Forest Service conducted its own, objective air quality impact analysis separate from IDEQ. However, it is recognized that the IDEQ is the regulatory authority in Idaho for air quality matters and any approval of the SGP permit application to the Forest Service would require compliance with IDEQ permit conditions.
von Lindern, Ian (Founder, Terragraphics International Foundation)	17436	11	<p>Perpetua and the Forest Service allege MoDPRO2 is a refinement of the earlier MoDPRO and PRO Alternatives, and addresses the insufficiencies identified in the DEIS. However, there are substantial and definitive differences with respect to the sources, toxicity, treatment, and disposition of COCs. In the Preferred Alternative, the SGP is not constrained to the production rates assumed by the Forest Service, but is permitted to increase production, emissions and environmental releases by 2.5 times, and could increase emissions by more than 3 times by amending a Minor Source Permit not subject to federal review. The Forest Service has neglected to consider there are adjacent resources available to SGP to substantially increase production.</p> <p>Conversely, the Forest Service has refused to consider Alternatives suggested by Public Reviewers.</p> <p>Among the more protective Alternatives are process options considered by Midas in the same time period the serial MoDPRO Alternatives were developed to address arsenic instability and exposure problems. These potential Alternatives, as noted below, are both technically and economical viable, and could substantially reduce the environmental burden of COCs.</p>	ALT	With regards to production rates, the commenter appears to be referring to permitting by the IDEQ and not the Forest Service. The Forest Service intends to require Perpetua to comply with the descriptions of its proposed operations as described in the 2021 MMP. If significant changes are proposed in the future to the 2021 MMP, the Forest Service would consider what additional environmental analyses would be required as part of the review and subsequent decision process of these proposed changes. The commenter alleges that the Forest Service did not consider other action alternates including: processing changes to reduce arsenic availability, offsite processing of gold concentrates, and consideration of CERCLA under the No Action Alternative. Inclusion of steps to reduce the environmental availability of arsenic in mill tailings are discussed in the Oxidation and Neutralization subsection of Section 2.4.5.7 of the SDEIS. More technical information related to the process designs are available in the 2021 MMP and the Feasibility Study Technical Report (M3 2021). The consideration of off-site processing of the gold concentrate is discussed in Section 2.6.2.1 of the SDEIS. Consideration of CERCLA applicability for the No Action Alternative is discussed in Sections 1.3 and 2.3 of the SDEIS.
von Lindern, Ian (Founder, Terragraphics International Foundation)	17436	12	<p>The Forest Service should reopen the Public Record and allow the same deference accorded the SGP to the Public. Appropriate alternatives should be identified in consultation with Public representatives, and addressed in a second, more objective, Supplemental DEIS. The Preferred Alternative should be re-evaluated on the basis of the design capacity of the facility, rather than on alleged production limitations.</p>	ALT	The Forest Service intends to require Perpetua to comply with the descriptions of its proposed operations as described in the 2021 MMP. If significant changes are proposed in the future to the 2021 MMP, the Forest Service would consider what additional environmental analyses would be required as part of the review and subsequent decision process of these proposed changes. The comment does not present significant new information relevant to the environmental concerns that have a bearing on the Proposed Action or its impacts.
von Lindern, Ian (Founder, Terragraphics International Foundation)	17436	31	<p>Off-Site Processing of Gold Concentrates: The issues associated with disposal of massive amounts of potentially unstable arsenic were repeatedly pointed out in the DEIS public comments. The Forest Service did not respond to these comments, but inserted vague references to a supposed HAC treatment system. Midas and the Forest Service did not disclose these problems and neglected to inform the public of an Alternative that could reduce toxic metals burdens to the environment by 50% - 80%. The 2021 Technical Feasibility Study also reveals that, at the same time Midas was conducting the HAC treatment tests, off site gold processing was being evaluated. This option would eliminate the POX/CL/Detox circuit and the arsenic stability challenges and would reduce the arsenic disposal burden at the site by more than 50%.</p> <p>The Forest Service evaluated and rejected Off-Site Gold Processing in Section 2.6.2.1 of the SDEIS that states: "Under this alternative, raw ore would be processed off-site and would reduce the amount of</p>	ALT	<p>Section 2.6.2.1 of the SDEIS does address potential offsite shipment of raw ore from the SGP for milling. It states that the environmental effects of approximately 550 round trips by truck per day to an offsite mill would be added to the offsite impacts of building the offsite mill facility to process the ore. This would clearly be a higher level of environmental effect than building and operating the proposed onsite mill facilities.</p> <p>The commenter states that offsite shipment of concentrate produced at flotation mills has been widely practiced. This does not invalidate the conclusion in Section 2.6.2.1 because a concentrator mill would still need to be constructed at the SGP to produce the concentrates.</p> <p>The commenter then focuses on the potential for production of the gold/silver concentrate and shipping it offsite for further processing instead of processing the concentrate on site. The commenter states the reason for this would be elimination of the POX/CL/Detox circuits and</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>reagents transported and used at the SGP, and the number of employees traveling to the site. It would also eliminate the need to store mill tailings at the SGP site. Transporting approximately 22,000 tons per day by trucks to an offsite mill would require approximately 550 round trips daily during the 15 years of mine operations. This would greatly increase the air emissions and transportation impacts of the SGP and dramatically increase operational costs. The main problem with this alternative is that there currently is no commercial milling operation in the U.S. West that could economically process the SGP ore. So, a new mill, with all the same associated environmental impacts as the proposed SGP on-site mill would need to be constructed.” (Emphasis added)</p> <p>It is uncertain whether this statement is naïve, facetious, or intentionally misdirecting. Raw ores were first, and perhaps last, shipped from Central Idaho Territory to Utah from Bayhorse in 1864 by pack train. For the last century, ores have been concentrated before shipping, usually at flotation mills built near the mine. In fact, simultaneous with addressing the arsenic stabilization problem, the 2021 Technical Feasibility Study states: “The potential for cleaner flotation to produce a concentrate suitable for shipment off-site, as an alternative to on-site sulfide oxidation and gold leaching, was investigated during the FS.”</p> <p>The 2021 Technical Feasibility Study also disclosed that pilot tests indicated that the processes were potentially technically and economically feasible, developed process flowsheets, and made recommendations for additional testing, should the alternative be pursued. As opposed to the one concentrate tested for HAC, variability testing was conducted on 13 different samples from all Pits, representing some of the “best and worst acting samples from the feasibility study.” Gold grades in concentrates were 40-50 g/t. “Average estimated supplemental loss in gold recovery was 3.3%, compared with the flotation of an on-site POX-ready concentrate.” This indicates a 25-30 fold concentration of Life-of-Mine (LOM) gold grades, reducing trucking to 20 loads/day at concentrate metals values comparable to the antimony concentrate Perpetua intends to ship to Asia or the Middle East.</p> <p>The 2021 Technical Feasibility Report continues. “A preliminary market study for gold concentrate sales was completed by an independent leading industry participant. The participant’s name has been withheld for confidentiality. In the study, the assumption was that the gold flotation concentrate would be shipped offsite to a regional processing facility located in Nevada where several autoclave and roaster plants are located...On May 9, 2018, Barrick Gold, which owns and operates (through the Nevada Gold Mines joint venture with Newmont) several roasters and autoclaves in Nevada, was granted a right of first refusal regarding purchase of gold concentrates as part of a financing arrangement were such concentrates to be shipped off-site.”</p> <p>Midas Consultants noted this Alternative was, potentially, technically and economically feasible with a substantial reduction in capital costs. This alternative would minimize, or eliminate, the highly toxic POX/CN leaching processes at Stibnite. This would reduce the total TSF arsenic disposal burden by >85% or by >350,000 tons, that would be disposed of in Class 1 facilities in Nevada. This would result in a 55% decrease in on-site disposal of arsenic, and elimination of labile As downstream of the flotation circuits.</p> <p>These undisclosed findings certainly suggest that Off-site Sale of Gold Concentrates meet the Alternatives criteria noted by the SDEIS: i) does the alternative, including a combination of component options, meet the purpose and need of the SGP? ii) does the alternative or component option potentially reduce environmental effects to at least one resource? iii) is the alternative or component option technically feasible? iv) is the alternative or component option economically feasible?</p>		<p>the arsenic stability challenges. Section 13.13.2 of the Feasibility Study (M3 2021) discusses the potential for production of a gold concentrate that could be shipped off site for further processing. The report describes that production of said concentrate would require a more complex and expensive gold flotation circuit than is currently planned for the SGP. Offsite toll processing of a gold concentrate would also require production of a cleaner, higher-grade concentrate at the SGP than would be necessary for the planned onsite gold extraction circuit, which would result in some additional loss of precious metal in the process. The Feasibility Report stated that, compared to production of a gold concentrate for onsite processing, cleaning the concentrate to shippable grades would result in a supplemental 3.3 percent loss of gold. With an estimated 4,217 koz of total recovered gold and 852 koz of silver from the proposed operations (Table 22.2 in M3 2021), this supplemental loss would be about 139,161 ounces of gold. Using the Base Case metal prices of \$1,600/oz for gold, this supplemental loss of gold would cost the project about \$223 million. This would not be consistent with the Project Purpose and Need.</p> <p>The commenter's stated benefit of the offsite processing of the gold concentrate was to eliminate the cyanide leaching on site and reduce the disposal of arsenic contained in the mill tailings in the onsite TSF. This would not result in a significant change in the environmental effects of the TSF already analyzed in the SDEIS because the proposed TSF is designed to prevent release of tailings to the environment during operations and post-closure. The proposed tailings management system also includes a cyanide treatment circuit to detoxify the cyanide in the tailings before disposal in the TSF.</p> <p>Narrative addressing offsite processing of a gold concentrate has been added to Section 2.6.2.1 of the Final EIS.</p>
von Lindern, Ian (Founder, Terragraphics International Foundation)	17436	32	<p>No Action alternative should consider CERCLA: This site is also subject to CERCLA, although it has not risen to priority status by the State of Idaho at this time. CERCLA-related actions are ongoing and are more likely to proceed, based on the outcome of the DEIS, and USFS, State of Idaho and Nez Perce Tribe considerations. Based on preliminary investigations undertaken, and other sites involving PRPs for this site in adjacent States, it is probable this site will achieve active status in the foreseeable future. Imposition of CERCLA, would be among the first steps require a conceptual site model that includes an</p>	ALT	<p>Consideration of CERCLA applicability for the No Action Alternative is discussed in Sections 1.3 and 2.3 of the SDEIS. Consideration of off-site processing of gold concentrates is discussed in Section 2.6.2.1 of the SDEIS which was characterized as potentially having overall environmental impacts greater than the 2021 MMP and an increase in operating costs significantly impacting Project economics. There is no need to disregard Perpetua's purpose</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			accurate and transparent material and contaminant balance for the site. Evaluation of such a model would be incumbent on the State, Tribal and federal trustees to resolve remedial requirements and CERCLA liabilities in, either Consent Decrees or implementation of voluntary cleanups, as part of mine development, reclamation, and closure. The Forest Service should include Off-site Processing of Gold Concentrates and CERCLA Cleanup as Alternatives in a more objective Supplemental DEIS.		and need for the Project and to develop alternatives that may be purely conjectural and whose implementation would be remote and speculative.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	7	As a result of these serious deficiencies, we urge the Forest Service to select the “No Action” alternative, and pursue timely clean up of legacy pollution via ongoing CERCLA actions. This is the only option that protects the watershed from more expansive harm from large-scale cyanide leach gold mining. Should the Forest Service not endorse the “No Action” alternative, we urge the agency to complete a revised SDEIS, with stand-alone supporting documents, to address these substantive issues and provide a more realistic and thorough analysis of the potential impacts of the Stibnite Gold Project.	ALT	The specific comments included in this comment letter are responded to in other comment/response for this and other comment categories. No further response is required here. General in nature or position statement.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	10	II. REVISED PLAN OF OPERATIONS The revised Plan submitted by Perpetua in October 2021 is considered to be the Proposed Action, also known as the 2021 Modified Mine Plan (MMP), and would consist of cyanide leach mine operations, including an open pit hard rock mine and associated processing facilities, located within Valley County in central Idaho on federal, state, and private lands (Figure ES-1). The SGP would have a projected life (construction, operation, closure, and reclamation), not including post-reclamation monitoring, of approximately 20 years, with active mining and ore processing occurring over approximately 15 years. The following mine components would be common to the revised plan and the two action alternatives: <ul style="list-style-type: none">● Mine pit locations, areal extents, and mining and backfilling methods● Transportation on existing and proposed roads● Pit dewatering, surface water management, and water treatment● Ore processing● Lime generation● Tailings storage facility (TSF) construction and operation methods● TSF buttress construction methods● Water supply needs and uses● Management of mine impacted water and stormwater runoff● Stibnite Gold Logistics Facility (SGLF)● A road maintenance facility● Surface and underground exploration● Worker housing facility	ALT	No further response is required here. General in nature or position statement.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	11	The SDEIS analyzes just one action alternative for the mine plan and two alternatives regarding access from Landmark, Idaho to the mine site. The 2021 MMP alternative would utilize the Burntlog Route as the primary access during the last year of construction, mining and ore processing operations, and closure and reclamation. The Burntlog Route Alternative would be 38 miles long and would require improving 23 miles of existing roads and constructing 15 miles of new roads. The Johnson Creek Route Alternative would use the existing Johnson Creek road from Landmark to Yellow Pine and the existing Stibnite Road from Yellow Pine to the mine site at Stibnite. This alternative would require upgrading sections of these roads, would add two years of construction time and would not require any new road construction.	ALT	The Final EIS includes the No-Action Alternative, the Johnson Creek Route Alternative, and the 2021 MMP, which represent a reasonable range of alternatives. As described in Section 2.6, “Alternatives Considered but Eliminated from Detailed Study,” the Forest Service considered a broad range of alternatives that were ultimately dismissed from further detailed study for the reasons cited in Section 2.6. As described in Section 1.7, “Federal Decision Framework,” in the Final EIS, part of the Forest Service’s decision is to determine whether approval of an alternative would require any changes or additions to mitigate impacts or satisfy applicable authorities. As such, the Final EIS includes a variety of detailed monitoring and mitigation measures that would be applied to the selected alternative to mitigate potential adverse effects from implementing the alternatives.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	27	E. The SDEIS fails to include essential information and project designs. The SDEIS completely omits critical information for the evaluation of the impacts of the Stibnite Gold Project. Some of these items include:	ALT	In preparing an EIS, the Forest Service attempts to evaluate reasonably foreseeable environmental effects and seeks information from the proponent and other sources that allow these evaluations to reasonably be made. The Forest Service believes it has accomplished this for the SGP EIS. It is a usual process for projects such as this that more detailed design and state permitting documents are prepared during the same period that the EIS is being

			<ul style="list-style-type: none"> ● An analysis under the CWA 404(b)(1) guidelines ● A detailed reclamation plan ● Plans and analysis of underground exploration (Scout Prospect Tunnel) ● A description of financial assurance calculations ● Designs of the transmission line upgrades and construction ● A fugitive dust control plan ● Sediment modeling ● Cyanidation facility permanent closure plan <p>This reliance on future studies and design plans violates NEPA, as NEPA’s entire purpose is to ensure that environmental considerations are taken into account before a decision is reached. The Forest Service should have obtained--and Perpetua should have provided--all this information before issuance of the SDEIS. Without the missing information, the Forest Service and the public cannot assess the full impacts of the project or meet the basic requirements of NEPA.</p>		completed. That is because the state permits often address exact design and operating descriptions whereas the EIS does not require this level of specificity to describe the reasonably foreseeable environmental effects of the entire Project.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	64	<p>IX. THE SDEIS VIOLATES NEPA</p> <p>A. The SDEIS fails to consider a reasonable range of alternatives Under NEPA, federal agencies are instructed to “inform decisionmakers and the public of the reasonable alternatives which would avoid or minimize adverse impacts or enhance the quality of the human environment.” 40 C.F.R. § 1502.1 (1978). NEPA requires an EIS to describe and analyze “every reasonable alternative within the range dedicated by the nature and scope of the proposal.” Alaska Survival v. Surface Transp. Bd., 705 F.3d 1073, 1087 (9th Cir. 2013). Consideration of alternatives “is the heart of the [EIS],” and agencies should “[r]igorously explore and objectively evaluate all reasonable alternatives” that relate to the purposes of the project and briefly discuss the reasons for eliminating any alternatives from detailed study. Id.; 40 C.F.R. § 1502.14 (1978).</p> <p>While an EIS “need not consider an infinite range of alternatives, only reasonable or feasible ones,” the failure to examine a reasonable range of alternatives renders an EIS inadequate. Id. See also Idaho Conservation League v. Lannom, 200 F. Supp. 3d 1077, 1090–91. (Payette National Forest violated NEPA by failing to discuss in the SDEIS any alternatives that reduced ground disturbing mining activities while still meeting purpose and need). In discussing alternatives, the Forest Service must state how the alternatives “will or will not achieve the requirements of... other environmental laws and policies.” 40 C.F.R. § 1502.2(d). A failure to consider a reasonable range of alternatives or “present complete and accurate information to decision makers and to the public” regarding the alternatives will violate NEPA. See Natural Resources Def. Council v. U.S. Forest Serv., 421 F.3d 797, 813–14 (9th Cir. 2005).</p> <p>An agency derives its project alternatives from the environmental impact statement's “purpose and need” section, which defines “the underlying purpose and need to which an agency is responding in proposing the alternatives including the proposed action.” City of Carmel-by-the-Sea, 123 F.3d at 1155; 40 C.F.R. § 1502.13. The reasonableness of an alternative is governed by a given project's “purpose and need.” Id. Agencies enjoy considerable discretion in defining the purpose and need of a project. Friends of Southeast's Future v. Morrison, 153 F.3d 1059, 1066 (9th Cir. 1998). However, in doing so “an agency cannot define its objectives in unreasonably narrow terms.” City of Carmel-by-the-Sea, 123 F.3d at 1155.</p> <p>As set forth below, the SDEIS fails to consider a reasonable range of alternatives, and it improperly dismisses viable alternatives from consideration.</p>	ALT	The purpose and need statement in Section 1.6, “Purpose of and Need for Action,” in the Final EIS describes the purpose and need for the Forest Service, which is appropriate given the proposed mining plan of operations and the Forest Service’s decision-making space. The Final EIS includes the No Action Alternative, the Johnson Creek Route Alternative, and the 2021 MMP, which represent a reasonable range of alternatives. As described in Section 2.6, “Alternatives Considered but Eliminated from Detailed Study,” the Forest Service considered a broad range of alternatives that were ultimately dismissed from further detailed study for the reasons cited in section 2.6. As described in Section 1.7, “Federal Decision Framework,” in the Final EIS, part of the Forest Service’s decision is to determine whether approval of an alternative would require any changes or additions to mitigate impacts or satisfy applicable authorities. As such, the Final EIS includes a variety of detailed monitoring and mitigation measures that would be applied to the selected alternative to mitigate potential adverse effects from implementing the alternatives.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	65	For example, the SDEIS does not provide adequate justification for eliminating underground mining as an alternative to be considered in the SDEIS. Unlike the Feasibility Study, which aggressively promotes the possibility for underground mining to potential investors, the SDEIS avoids serious discussion of underground mining as a possibility. Underground mining is declared to be uneconomic, but there is no quantitative information provided in the SDEIS to defend that supposition. The potential for underground mining should be viewed first in the light of a choice as an environmentally preferable	ALT	As stated in section 2.2.2 of the SDEIS, potential alternatives and component options were screened based upon four criteria. Underground mining was considered but eliminated from further detailed study in the SDEIS for the reasons discussed in Section 2.6.1.1.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			SDEIS alternative. Underground mining would mean less waste disposal on the surface, and less disruption of existing surface water flows, while still allowing removal of the existing source of contamination proposed for the open pit mining alternative. In the haste to eliminate underground mining as a consideration, a potential environmentally preferable option is not being properly analyzed.		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	66	Further, the SDEIS does not include an alternative that examines a dry stack tailings facility or a mining footprint limited to the existing footprint of previous disturbance. Given the significant negative issues of placing the Tailings Storage Facility in the upper Meadow Creek streambed, wetlands, and RCAs, the Forest Service should develop an alternative that essentially limits tailings production to the volume that can be safely stored without inundating wetlands, RCAs or streams. Thus, the limiting factor for mining would be tailings storage. Once all the suitable, non-sensitive areas are used for tailings storage sites, mining should cease.	ALT	The 2021 MMP describes Perpetua's primary objectives based on professional examination of the mineral reserves, economics, and common sense. The SGP mine plan was designed to reasonably produce the target metals with an economically efficient operation. Therefore, the Project is based on economic and profitable production of the recoverable metal values, without consideration of limiting this mining to the amount of tailings produced. There is no need to disregard Perpetua's purpose and need for the Project and to develop alternatives that may be purely conjectural and whose implementation would be remote and speculative. Section 2.6.2.2 of the SDEIS describes consideration of dry stack tailings and the reasons why this alternative was eliminated from further detailed analysis. Section 2.6.3.1 of the SDEIS discusses multiple TSF alternative locations and sizes that were considered but eliminated from further consideration for the reasons stated.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	67	We also recommended developing an alternative in which the tailings and/or waste rock are relocated back into the main pits (or other geologically stable area). While rehandling this material would require additional expense, the Forest Service should compare this with the cost of dealing with a catastrophic dam failure, contamination, and effects of downstream public health and fisheries issues. We appreciate rounding the crests and utilizing variable slope angles of waste rock piles to blend in with natural landforms where this can be done without compromising stability or integrity of the waste rock piles.	ALT	Handling of development rock is described in Section 2.4.5.5 of the SDEIS. Table 2.4-9 shows the amounts of development rock that would be placed back into the open pits. Other development rock would be used to construct the TSF embankment and the TSF buttress. Tailings from the SGP mill must be placed in a TSF that meets the requirements of the Idaho cyanidation regulations which require engineered liners to minimize leakage of water from the deposited tailings. It would be impractical to construct such a liner in the steep and rocky interior of an open pit. Additionally, it would be very impractical to deposit tailings in an open pit during active mining operations. The Tailings Storage Facility and TSF Buttress subsection of Section 4.2.2.2 of the SDEIS describes the geotechnical stability of the proposed TSF and shows that it would have a high degree of geotechnical stability such that consideration of a catastrophic failure of the TSF embankment would be a worst-case assumption not required under NEPA.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	68	Related to reducing the footprint of mine operations, the Forest Service should assess how utilizing 85 ton mine trucks instead of 200 ton mine trucks would reduce the size of the roads that would be needed to support mine operations.	ALT	In the case of the SGP, a number of haul truck sizes were considered as discussed in Section 16.3.4 of the 2021 Feasibility Study (M3 2021) and 100-ton trucks were found to be inefficient for production mining.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	69	Given Perpetua's recent statements that antimony production is one of the primary goals and the grant from the Department of Defense, the Forest Service should develop an alternative emphasizing antimony recovery. In the SDEIS, it is noted that only 15 to 20% of the total mill feed would contain sufficient antimony mineral grades to warrant production of antimony concentrate. We suggest developing an alternative focused on only developing the ore that contains high antimony mineral grades. This mineralized area would still contain some gold and silver but could dramatically reduce the footprint, wetlands impacts, and water treatment costs. Perpetua has already received a subsidy to mine this material so there is no longer a need to fully fund this project through gold extraction.	ALT	The 2021 MMP describes Perpetua's primary objectives based on professional examination of the mineral reserves, economics, and common sense. The mine plan was designed to reasonably produce the target metals with an economically efficient operation. Figure 22.2 of the 2021 Feasibility Report (M3 2021) shows the relative payable metal value for the three target metals and clearly demonstrates that the gold value dominates over the antimony and silver values. Therefore, limiting the Project to only the antimony production would severely impact the economics of the SGP. There is no need to disregard Perpetua's purpose and need for the Project and to develop alternatives that may be purely conjectural and whose implementation would be remote and speculative.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	70	As an alternative to the proposed transmission line route from Johnson Creek substation to the mine site along an old and revegetated transmission line route from the 1940's, the Forest Service should develop an alternative constructing this transmission line along the Johnson Creek/Stibnite Road. This route would avoid the need to clear a 100-foot swath of vegetation for 9.1 miles and reconstruct a new access road and also make transmission line maintenance and decommissioning easier. Another ROW alternative that the Forest Service should consider is the old Thunder Mountain Road. The road prism is in place but water management features such as water bars are needed. Furthermore, the SDEIS fails to include an alternative that considers early closure or long-term cession of mining activities due to the sequence of ore production anticipated for the SGP and/or inherent	ALT	Section 2.6.3.1 of the SDEIS discusses alternative power line configurations between the proposed Johnson Creek substation and the mine site and the reasons why they were eliminated from detailed study in the EIS. It is the Forest Service's intention that the permanent closure characteristics described in Section 2.4.7 of the SDEIS would be achieved. Temporary closure of the operations is included in Section 2.4.5.15 of the SDEIS. This section describes what actions would continue during a temporary closure of the facilities to maintain compliance with commitments for monitoring and environmental compliance. It also states that compliance with the proposed permanent regulatory closure characteristics would be required, unless modified by the required regulatory authorities. The 2021 Feasibility

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			volatility of gold prices. Perpetua’s 2021 Feasibility Study indicates that Mill Feed and Gold Head Grade peaks at production year 4 before sharply declining for the remaining 11 years of the life of the mine.124 Notably, while the average gold grade (g/t) declines over time, the amount of development rock that must be removed to reach the lower grade ores increases.125 In short, the SGP becomes a less profitable mining operation overtime.126 Given uncertainty in gold, silver, and antimony prices, early closure is a reasonably foreseeable possibility for the SGP. Even if an early closure alternative is not developed, the SDEIS must address how long the mine will remain idle (i.e., in “care and maintenance”) before the operator is required to enter a permanent closure phase. This is critically important because the anticipated “back-filling” of both the Hangar Flats Pit and the Yellow Pine Pit as well as other reclamation activities (backfilling the Midnight Pit) rely on development rock mined from the SGP’s lowest grade deposit within the West End Pit.127 If mine sequencing fails to follow that which is proposed in the 2021 MMP, the whole plan falls apart and the Payette National Forest is back to square one with even deeper and more giant holes in the ground than currently exist. Failure to plan, is planning to fail. The SDEIS must consider and evaluate plans for early closure at critical mining phases that if not achieved would significantly impact the mine operator’s ability to perform proposed restoration and reclamation actions128—actions this SDEIS assumes are events that will occur.		Report (M3 2021) describes the economic risk analysis for the Project as designed and utilizes a base case gold price of \$1,600/oz. using the 3-year trailing price (60%) and the 2-year futures price (40%). The gold price in the last three years has ranged from about \$1,650/oz. to over \$1,900/oz. The economic analysis for the SGP utilized five metal price cases for gold from a low of \$1,350/oz. to a high of \$2,350 oz. At the low price point for gold, the payback period for the Project was less than 4 years and the internal rate of return before taxes was just over 17%. The situation described in the comment that gold and silver pricing could drop in the future to a point where continued mining at the SGP would be terminated early is considered speculative and not foreseeable. There is no need to disregard Perpetua's purpose and need for the Project and to develop alternatives that may be purely conjectural and whose implementation would be remote and speculative.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	71	As recounted in these comments, there are a number of other significant resource issues that will be adversely affected by the proposal that should have been the basis for the development of additional alternatives. These resource issues include the destruction of whitebark pine trees, degradation of the Frank Church River of No Return Wilderness (FCRNRW), wetlands, and water quality, the mobilization of arsenic in the environment, and the lengthy and unknown rate of restoration and ecological recovery after the mine’s closure.	ALT	The effects of the Project on resources such as whitebark pine (SDEIS Section 4.10.2.2), wilderness (4.23.2.2), wetlands (4.11.2.2), water chemistry including arsenic (4.9.2.2), and reclamation (4.5.2.2) are described in the SDEIS. These effects are the subject of design features, Forest Service requirements, and mitigation measures rather than alternatives because action alternatives meeting the Project's purpose and need would experience these effects.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	72	lengthy and unknown rate of restoration and ecological recovery after the mine’s closure. 1. The refusal to consider any alternatives to “the Mining Portion” of Perpetua’s proposed mine violates NEPA The SDEIS (p. 2-2) considers only two action alternatives: the 2021 MMP (Perpetua’s proposal); and the Johnson Creek Route Alternative. While the Johnson Creek Route Alternative considers a different access route to the site, there is no other difference. As the SDEIS states: “The mining portion of this alternative would be the same as the 2021 MMP.” Id. There is no difference between these two action alternatives when it comes to: <ul style="list-style-type: none"> ● Mine pit locations, areal extents, and mining and backfilling methods; ● Transportation management on existing and proposed roads ● Pit dewatering, surface water management, and water treatment ● Ore processing ● Lime generation ● Tailings storage facility (TSF) construction and operation ● TSF buttress construction methods ● Water supply needs and uses ● Management of mine impacted water and stormwater runoff ● Electrical transmission lines ● Stibnite Gold Logistics Facility (SGLF) ● A road maintenance facility ● Surface and underground exploration ● Stibnite Gold Project worker housing facility SDEIS, p. 2-3. Perpetua’s proposal is for mining. While alternative access routes are an important consideration, it is “the mining portion” of Perpetua’s proposal which will have the greatest number of, the most severe, and the longest lasting environmental impacts. Yet, the SDEIS fails to consider any alternatives related to any aspects of “the mining portion” of Perpetua’s proposal. This violates NEPA. To consider a	ALT	The 2021 MMP describes Perpetua's primary objectives based on professional examination of the mineral reserves, economics, and common sense. CEQ has stated that "Reasonable alternatives include those that are practical or feasible from the technical and economic standpoint and using commonsense, rather than simply desirable from the standpoint of the applicant." (40 Most Asked Questions Concerning CEQs NEPA Regulations, Q/A 2a, 51 FR 15618, April 25, 1986). CEQ has also stated, "an agency's responsibilities to examine alternatives sites has always been bounded by some notion of feasibility" and, "there is no need to disregard the applicant's purpose and needs and the commonsense realities of a given situation in the development of alternatives" (CEQ Guidance Regarding NEPA Regulations, 48 FR 34263, July 28, 1983). The 2021 MMP mine plan describes Perpetua's primary objectives based on professional examination of the mineral reserves, economics, and common sense (M3 2021). The Project mine plans are based on economic and profitable production of the recoverable metal values, constrained by the site-specific physical conditions at the site such as geology, mineralization, topography, hydrology, and in this case, the legacy mining features. Section 2.6 details the alternatives considered but eliminated from detailed study.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>reasonable range of alternatives, the Forest Service must consider one or more alternatives to “the mining portion” of Perpetua’s proposal, such as alternatives to: mine pit locations and extents; mining and backfilling methods; pit dewatering, surface water management, and water treatment; ore processing; and TSF construction and operation. These are major, controversial issues with huge and lasting environmental implications; yet, the SDEIS does not consider any alternatives with any difference when it comes to these issues.</p> <p>In the August 2020 DEIS, the Forest Service did consider two additional alternatives to “the mining portion” of Perpetua’s proposal. See SDEIS ES-1. But in the SDEIS, Forest Service eliminated those alternatives from further consideration and is no longer considering any alternatives to “the mining portion” of Perpetua’s proposal. Id. Without considering any alternatives to “the mining portion” of Perpetua’s proposal, the Forest Service is not considering a reasonable range of alternatives as required by NEPA. Additionally, the Forest Service improperly dismissed viable alternatives proposed in public scoping comments and at other points which would satisfy the purpose and need of the project and could reduce the adverse environmental impacts, as discussed next for some of these potential alternatives.</p> <p>a. Underground alternative</p> <p>As described in CSP2 (2022), the SDEIS does not provide adequate justification for eliminating underground mining as an alternative to be considered in the SDEIS. In explaining why underground mining was eliminated as a consideration in the SDEIS, the rationale presented begins by asserting: “In aggregate, grades for these three deposits above a 0.48 grams per ton (g/t) gold cut-off grade averaged 1.43 g/t gold, 1.91 g/t silver, and 0.064 percent antimony (M3 2021). Typical economic cutoff grades for underground mine operations are approximately 5 g/t gold.” (SDEIS 2022, emphasis added)</p> <p>The basic consideration for potential economic viability must begin by considering how much gold that is greater than the cutoff grade has been identified, and whether this amount would justify underground mining. This is not addressed in the SDEIS analysis.</p> <p>In addition, if underground mining were to take place, the cutoff grade would likely be less than the 5 g/t proposed in the SDEIS. The reference cited in the SDEIS, the Stibnite Gold Project Feasibility Study (M3 2021), has an entire section devoted to the discussion of “Potential high-grade underground exploration prospects” (M3 2021, Section 9.8). In that section M3 used “gold cutoff” values of 2.4 g/t and 3 g/t, both of which are well below the 5 g/t cited in the SDEIS. The SDEIS does not give a citation for its choice of 5 g/t as “Typical economic cutoff grades for underground mining...”. The 5 g/t cutoff grade is not mentioned in the Feasibility Study. The choice of a typical cutoff grade for underground mining in the SDEIS should at least be consistent with the information being presented to the company’s potential investors in its technical reports.</p> <p>Unlike the Feasibility Study, which aggressively addressed the possibility for underground mining to potential investors, the SDEIS appears to avoid serious discussion of underground mining as a possibility by proposing underground mining is economically unfeasible, then failing to defend that premise with any quantitative analyses.</p> <p>The potential for underground mining should also be viewed in the light of a potential choice as an environmentally preferable SDEIS alternative. Underground mining would mean less waste disposal on the surface, and less disruption of existing surface water flows, while still allowing removal of much of the existing waste sources of contamination proposed for the open pit mining alternative. The SDEIS should also consider this alternative in terms of reduced impacts to soils. Section 4.5.2.2 indicates that Total Soil Resource Commitment (TSRC) guidelines in the PNF Forest Plan to limit TSRC to 5% of activity area would be violated with the project leading to a TSRC of 17%. Reclamation activities would not reduce this amount as noted on p. 4-78:</p> <p>“As a general rule, the processes responsible for restoration of soil productivity occur over a very long timeframe (centuries to millennia) and do not directly correlate to successful reclamation, which is mainly oriented to short-term objectives.”</p>		

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>And, “Thus, the recovery of greater than 40 percent soil productivity within a 50-year timeframe is unlikely (Forest Service 2022c).”</p> <p>This conclusion led the Forest Service to propose a Forest Plan Amendment (FPA) which would waive the TSRC guidelines. The Forest Service should consider whether an underground alternative would reduce these unacceptable impacts to soils and the deficit in available reclamation materials. In the haste to eliminate underground mining as a consideration, a potential environmentally preferable option is not being properly analyzed.</p>		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	73	<p>b. Utility corridors</p> <p>The SDEIS fails to consider any alternatives to the utility corridor to reduce potential impacts. For example, at the proposed Montanore Mine in Montana, multiple alternatives to the proposed utility corridor were proposed, with detailed comparisons, to determine which alternative would reduce impacts to important fish and wildlife resources.129</p>	ALT	Section 2.4.4.7 of the SDEIS described the electric transmission line that would supply power to the SGP. Approximately 59 miles of this line would be an upgrade of existing transmission lines from Lake Fork to the proposed Johnson Creek substation. The existing transmission lines are owned by Idaho Power Company and they have a right-of-way from the Forest Service for the lines. Idaho Power has proposed to upgrade these lines so there are no alternatives to these existing alignments. For the SGP, approximately 9 miles of new transmission line would connect the Johnson Creek substation to the mine. Section 2.6.3.2 detailed two potential alternative alignments that were considered for the newly constructed power line proposed from the Johnson Creek area into the mine and the reasons why these alignments were eliminated from further detailed analysis.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	74	<p>c. Off-site processing of gold concentrates</p> <p>The Forest Service evaluated and rejected Off-Site Gold Processing in Section 2.6.2.1 of the SDEIS that states:</p> <p>Under this alternative, raw ore would be processed off-site and would reduce the amount of reagents transported and used at the SGP, and the number of employees traveling to the site. It would also eliminate the need to store mill tailings at the SGP site. Transporting approximately 22,000 tons per day by trucks to an offsite mill would require approximately 550 round trips daily during the 15 years of mine operations. This would greatly increase the air emissions and transportation impacts of the SGP and dramatically increase operational costs. The main problem with this alternative is that there currently is no commercial milling operation in the U.S. West that could economically process the SGP ore. So, a new mill, with all the same associated environmental impacts as the proposed SGP on-site mill would need to be constructed.” (Emphasis added)</p> <p>However, the 2021 Technical Feasibility Report disclosed that pilot tests showed that the processes were technically and economically viable. Furthermore, that report indicated, “Average estimated supplemental loss in gold recovery was 3.3%, compared with the flotation of an on-site POX-ready concentrate.” This implies a 25 to 30-fold concentration of LOM gold grades, reducing the required trucking to 20 loads/day (versus the 550 loads/day referenced by the SDEIS) at concentrate metals values comparable to the antimony concentrate Perpetua intends to ship to Asia or the Middle East to be processed.</p> <p>This alternative would minimize, or eliminate, the highly toxic POX/CN leaching processes at Stibnite. This would reduce the total TSF arsenic disposal burden by >85% or by >350,000 tons, with the remainder of the arsenic burden being disposed of in Class 1 facilities in Nevada rather than the sensitive headwaters of the EFSFSR. This would result in a 55% decrease in on-site disposal of arsenic, and elimination of labile As downstream of the flotation circuits.</p> <p>These findings certainly suggest that off-site processing of gold concentrates meet the Alternatives criteria noted by the SDEIS: i) Does the alternative, including a combination of component options, meet the purpose and need of the SGP (yes), ii) Does the alternative or component option potentially reduce environmental effects to at least one resource (yes), iii) is the alternative or component option technically feasible (yes), and iv) is the alternative or component option economically feasible (yes).</p> <p>The Forest Service should include off-site processing of gold concentrates as an alternative in a revised Supplemental DEIS.</p>	ALT	Section 2.6.2.1 of the SDEIS discusses the off-site processing of raw ore to eliminate the need for a mill, TSF, and associated infrastructure and employees at the SGP. Regarding the first alternative suggested by the commenter, production of a gold/silver concentrate at the SGP that should be shipped to an off-site facility to extract the gold and silver from the concentrate, this would still require an on-site mill, TSF, and associated infrastructure but would eliminate the need for the on-site POX and CN circuits. The main benefit of this alternative asserted by the commenter would be to reduce labile arsenic in the on-site TSF. Because the TSF is designed to operate with no discharge of tailings downstream in any case, this alternative would not change the reasonably foreseeable environmental impacts of the Project.

Ronn Julian	17666	1	<p>Thank you for the opportunity to provide comments on the Stibnite Gold Project. It is hard to imagine the lapse in time since the DEIS was released for comment, but it is not too much of a surprise. When I reviewed the DEIS, it just never seemed possible for that group of action alternatives to make the grade. The scope of development and the magnitude of land disturbing activities was just too great to make it through the entire process. Please recall that I am unique in terms of commenters given my nearly two decades as the Cascade District Ranger and having worked for Midas Gold Idaho both as a consultant and a public affairs employee and eventually as a member of the Board of Directors. I found the experience gained at these two employment arenas provides me with some valuable insight with regards to this project and this environmental review process.</p> <p>Consequently, I responded to the initial call for public comments way back when. My comments were directed to provide the foundation for an important analysis done well so that there were no re-starts. While my comments were not fully appreciated by the Company, I was satisfied they might help the process. Unfortunately, that has not been what I have seen unfold. There has been a tendency on behalf of some agency staff to not engage in terms of advice to the Company by pointing out trade-offs and suggesting alternate ways to accomplish objectives. And likewise on the proponent side, there has been a level of frustration based in a large part to a fundamental misunderstanding of NEPA and all the trappings that go with it. I would describe the relationship to have been contentious at some points. Collectively, these elements have made progress challenging. What you have before you now was born of that difficult relationship.</p> <p>I hard copy mailed my DEIS comments in on 10/24/20 as I had lost internet service. Upon returning from two weeks in Alaska, I checked your public reading file and did not find my comment letter. I recall speaking to Brian Harris about the absence and he indicated it does take some time for hard copy letters to be incorporated into the data base. He indicated that he would look into the matter. I never did hear back from him and am not certain whether it is in the data base at this point. Hence, I have included it with this letter.</p> <p>The major concerns that I saw with the DEIS was the range of alternatives and the potential for jeopardy biological opinions. In my judgement, the range was far too narrow given the possibilities. The possibilities that exist with this project are not numerous, but are quite different in terms of effects. As I reviewed the SEIS, I arrive at the same conclusion. This project analysis will be subjected to a high level of scrutiny and will most likely undergo litigation. I honestly believe the range of alternatives will not pass the “robust analysis of a broad range of alternatives” test. The sophisticated character of some of the potential litigants is rather daunting and will play an important part of the judicial process. This project cannot move forward without a much improved analysis.</p>	ALT	SDEIS Sections 2.2 and 2.6 describe the development of Project alternatives and the rationale for consideration in the NEPA analysis. The determinations of the biological opinion would be based on the Agency Preferred Alternative and would be incorporated into the Forest Service decision on the Project.
Ronn Julian	17666	3	<p>I encourage you to enhance the “robust analysis on a broad range of alternatives” so that you are highly informed as the Responsible Official and that the regulatory process can withstand the test of adequacy it is surely going to receive. For example:</p> <p>Develop a design feature that employs the SFSR road as the mine access for the winter months for the construction period of the mine. It completely eliminates the need to construct the parallel snowmobile trail along upper Johnson Creek Road. No short-term effect on existing wintertime recreation. Winter loads during the construction period on the SFSR Road will generally be non-hazardous in nature and consist mainly of building supplies and plant construction products. The SFSR Road offers an all-surface road during the winter months that will minimize potential vehicle accidents and it is mostly located in a low snowfall belt which translates to a lower cost to maintain. Design features such as requirements for convoys with pilot cars all mining traffic on a predetermined and advertised schedule; the fuel depot at the mine site should be full-to-the-rim come December; any use of the SFSR route for hazardous loads would be minimal and restricted to blue bird weather and ice-free road surfaces. The average winter season would be December thru March. The SFSR Road can easily handle that amount of freight and traffic. The benefit to Valley County would be the mining company taking over the cost of wintertime maintenance and the likely use of a motor grader instead of the 1-way plow currently used by the County. Note: the jurisdiction of the road rests with the USFS so a motor grader with a wing could be specified in the Road Use Permit. The additional time could be used to identify an alternative route for</p>	ALT	SDEIS Section 2.6 describes the consideration of alternatives including access routes.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			the snowmobile trail that might employ the use a portion of the Lunch Creek Road network and other suitable terrain away from the JC Road.		
Ronn Julian	17666	4	<p>1. Develop an alternative that upgrades the Johnson Creek Road (versus full reconstruction) to provide additional turn outs, passing lanes and include a mining traffic management plan* that addresses a schedule for inbound and outbound traffic, driver experience, vehicle configuration, and pilot cars. That road moved a great deal of mining traffic in the last burst of mining activity in the late 90's and early years of the new century. Design features could include paving the road through the town of Yellow Pine; paving or crushed aggregate along areas adjacent to streams and selected areas of dust abatement; reconstruction window for the lower reaches of the road during the winter months. There would be a similar but smaller scale need to upgrade the EFSR Road from YP to Stibnite. The possible development of the Antimony Cut by a separate mining company in the lower Johnson Creek area may be a foreseeable need that may fit well with this alternative. This alternative would provide quite a contrast on costs and disturbance quantities to the Burntlog route. The effects analysis would likely demonstrate a long-term need for a parallel snowmobile route that could be constructed in the same timeframe as the road improvements. In addition, there is time to evaluate alternative locations for the snowmobile route that may employ some of the road system in Lunch Creek and suitable terrain away from the JC Road. This alternative will provide quite a contrast in terms of the number of days it is far too stormy for any mine traffic on any roads in this area. It will likely show that the JC Road route is far more dependable than the Burntlog route that lies partly in the heaviest snowfall belt for miles around this part of Idaho. The deepest snowpack lies along the Pistol Ridge that towers over the Burntlog drainage. Note: I see no mention in any of the documents of the solution that will be employed when the Burntlog road is snowed-shut and unavailable for 5-7 days. The reader must conclude that the only other snow-free route is the SFSR road. This situation can and will occur every winter on more than one occasion.</p> <p>A mining traffic management plan must be developed and be included in the environmental review and supporting documents as a design feature. As a minimum, it will address and define the following: vehicle configuration such as triple axel flatbed, semi-trailer, pup trailer that will be used to haul to and from the mine (fuel trucks with pup trailers are not appropriate on these roads). Approved trucking operator standards (you simply cannot have unfamiliar drivers hauling random freight to the mine in over-the-road tractor/trailer combinations). A schedule for pilot car convoys and a predetermined and advertised inbound/outbound schedule. Further if the size of mine site overburden trucks at 200 tons is driving the access road standards to the mine, then the utility of 85 ton overburden trucks needs to be evaluated.</p>	ALT	<p>The Johnson Creek Route Alternative was developed and analyzed in the SDEIS. This alternative did not entail full reconstruction but the upgrades required for mine access use were substantial and included in the analysis.</p> <p>SDEIS Section 4.16 describes the Transportation Management Plan developed for the Project which includes descriptions of proposed road use and maintenance including measures to limit vehicle incidents. Full-size mining equipment would not operate on access roads.</p>
Ronn Julian	17666	4	<p>2. There are a couple of alternatives for the location of the electrical service line from the floor of Johnson Creek to Stibnite that deserve a look. The Riordan/Horse Heaven route that was used in the 1940's certainly was the shortest and was likely selected for that very reason. However, the circumstances we have today should not automatically opt for that route simply because one official at Idaho Power insists they still hold a permit for that location and convinced Midas managers that has to be the location of the line. That war-era line was decommissioned decades ago and there is no existing permit for a power line for that location. Again, lack of engagement by the land manager and the proponent coordinating with the Payette NF.</p> <p>a. One alternative location would be to build the line from Yellow Pine to Stibnite in the EFSR canyon. It is likely many of the tower locations could be accessed with short spurs off of the EFSR Road. The ground disturbance and costs would be quite a contrast to the Riordan route.</p> <p>b. A second alternative location would be to upgrade the 138KV only to the junction area of the Thunder Mountain Road (Twin Bridges on the BNF) and then follow a route adjacent to the TM Road to the Stibnite area. The TM Road is in a very depleted condition due to the 2007 high intensity wildfire in the headwaters of the drainage. This road with some reconstruction and rehabilitation work would offer very suitable</p>	ALT	SDEIS Section 2.6 describes the consideration of alternatives including powerline route options.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>access for powerline construction and maintenance vehicles. Recall, if the Burntlog route is chosen as the mine access route, much of the TM Road will be upgraded to a 28-foot roadway and that will greatly facilitate powerline access. There is sufficient terrain to locate the necessary switching station/transformer configuration in the in the Twin Bridges location. This alternative would eliminate the 138KV upgrade to the 11-mile line from Twin Bridges to Yellow Pine (as described in the preferred alternative).</p> <p>It is only prudent to look at the decision to feed the upgraded 138KV line from the single line that comes into Valley County from the power complex on the Snake River. Idaho Power's Comprehensive Study identified the need for a second line into the County that would feed in from the Ola area to the south. If the need for the loop is valid, there is no better time to look at that route in terms of time and cost. The astronomical figure that is being poured into the substation upgrades on the existing line (by Perpetua) is more than enough reason to question the wisdom of the northern route. That is potentially a lot of funding that could be put towards mine site design and mitigation. If nothing else, the disclosure requirement in the NEPA regulations would require the rationale for not opting for the south loop feed. This may seem like a minor detail but it is issues like these that are "eye candy" in the litigation process.</p>		
Ronn Julian	17666	4	<p>It was a bit of a surprise to me to not see an alternative in the SEIS that provided less processing of the ore bodies at the mine site which resulted in a "concentrated slurry" that contains all the various precious metals. During my time associated with Midas Gold, the Company pursued this option in great detail and preliminary results looked promising. The less-processed concentrate would be trucked out of the mine site to be refined in another location. The possible benefits to this alternative may have required less demand for electricity which may have negated the upgrade to 138KV and less processing etc. at Stibnite. It would seem to enhance the range of alternatives if this alternative received mention and consideration. I know sometimes that proponents view NEPA as something that has to be completed rather than a process that analyzes alternatives to quantify effects and help guide the decision process. I'd be curious if this work was ever disclosed to your office.</p>	ALT	<p>SDEIS Section 2.6 describes the consideration of alternatives including processing options.</p> <p>Section 13.13.2 of the Feasibility Study (M3 2021) discusses the potential for production of a gold concentrate that could be shipped off site for further processing. The report describes that production of said concentrate would require a more complex and expensive gold flotation circuit than is currently planned for the SGP. Offsite toll processing of a gold concentrate would also require production of a cleaner, higher-grade concentrate at the SGP than would be necessary for the planned onsite gold extraction circuit, which would result in some additional loss of precious metal in the process. The Feasibility Report stated that, compared to production of a gold concentrate for onsite processing, cleaning the concentrate to shippable grades would result in a supplemental 3.3 percent loss of gold. With an estimated 4,217 koz of total recovered gold and 852 koz of silver from the proposed operations (Table 22.2 in M3 2021), this supplemental loss would be about 139,161 ounces of gold. Using the Base Case metal prices of \$1,600/oz for gold, this supplemental loss of gold would cost the Project about \$223 million. This would not be consistent with the Project Purpose and Need.</p>
Benjamin Davenport, Executive Director, Idaho Mining Association	18777	11	<p>A. The No Action Alternative is Not Selectable</p> <p>IMA cannot fathom any circumstance in which it would be appropriate for the Forest Service to select the No Action Alternative as the Agency Preferred Alternative in the Final EIS. Selecting the No Action Alternative would preserve the environmentally degraded <i>status quo</i> and forego this unique opportunity to use private-sector resources to clean up the Stibnite Mine site.</p> <p>IMA suggests the Final EIS put more effort into discussing why the No Action Alternative is not selectable for the SGP because the SDEIS does not fully describe the numerous environmental restoration measures that would not be built and the environmental improvements that would not materialize under the No Action Alternative. For example, the No Action discussion in Section 4.12.2.1 does not mention that opportunities to eliminate the Yellow Pine Pit cascade barrier to fish migration and to reconnect over 21 miles of the EFSFSR would not occur under the No Action Alternative. Instead, this section states that no negative impacts to fish or fish habitat would occur if the MMP is not built and fails to acknowledge that habitat restoration and water quality benefits would be foregone without the project. This is an inaccurate and incomplete disclosure of the lost opportunity costs associated with the No Action Alternative.</p> <p>Similarly, the Executive Summary lacks a meaningful discussion of the environmental restoration and improvement opportunities that would not occur under the No Action Alternative. The No Action Alternative would mean that none of the numerous significant environmental restoration measures in the MMP (e.g., removing some of the legacy mine wastes that are contaminating area streams and eliminating the cascade that precludes fish migration immediately upgradient of the Yellow Pine Pit)</p>	ALT	<p>The current site conditions and the effects of previous mining that was unreclaimed are described in SDEIS Chapter 3. The effects analysis presented in Chapter 4 represents a comparison of predicted Project effects on environmental resources to the current conditions and describes those effects relative to the existing conditions. As described in SDEIS Section 2.7, these comparisons form the basis for selection of the 2021 MMP as the Agency Preferred Alternative.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			would occur. Both the Executive Summary and the resource sections in Chapter 4 of the Final EIS should more fully describe how the No Action Alternative would perpetuate the existing degraded environmental conditions at Stibnite.		
Benjamin Davenport, Executive Director, Idaho Mining Association	18777	12	<p>B. The Agency Preferred Alternative</p> <p>There are obvious environmental and safety reasons why the Burntlog Route is clearly preferable to the Johnson Creek Route Alternative. Therefore, IMA strongly supports the Forest Service's decision to select the Burntlog Route as the Agency Preferred Alternative in the SDEIS. The SDEIS calls this alternative the "2021 Modified Mine Plan (MMP) Alternative." (This is the transportation route that Perpetua proposes in its updated "ModPRO2" Plan of Operations.)</p> <p>As documented in the SDEIS, the Burntlog Route Alternative has fewer environmental risk factors compared to the Johnson Creek Route Alternative. Because the Johnson Creek Route is closer to fish-bearing streams than the Burntlog Route, there is a higher potential for adverse impacts to water quality in the event of a fuel or chemical spill or leak from a delivery truck. Also, regular use of the Johnson Creek Route would increase sedimentation impacts.</p> <p>Additionally, the Burntlog Route has fewer safety concerns than the Johnson Creek Alternative. There are several large avalanche paths along the Johnson Creek Route, which make it an unsafe choice for routine winter use. Because it will not be possible to realign the route to completely avoid the avalanche paths, the road would probably have to be closed during high-risk avalanche conditions. Such road closures would create obvious operational constraints and could also precipitate an emergency if project personnel are unable to leave the mine site or if emergency vehicles cannot reach the site. The inevitability of unpredictable avalanche events would obviously pose a direct and serious risk to people driving this route who could be caught in an avalanche.</p> <p>For these reasons, IMA recommends that the Forest Service select the Burnt Log Route as the Agency Preferred Alternative in the Final EIS.</p>	ALT	No further response required. General in nature or position statement.
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	1	Clearly and sharply defining impacts from the mine access routes/road alternatives.	ALT	The specific comments included in this comment letter are responded to in other comments/responses for this and other comment categories. No further response is required here. General in nature or position statement.
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	11	<p>Alternatives Analysis – Burntlog Route and the Johnson Creek Alternative</p> <p>The material summarized in the Executive Summary and in Table 2.8.1 Alternative Comparison and Impact Summary¹ indicate that the Burntlog Route may result in greater impacts on several environmental and economic indicators, than as generally presented for the 2021 MMP Alternative (which includes the Burntlog Route). Examples include more greenhouse gas (GHG) emissions, soil impacts, stream crossings, forest disturbance, wetland loss, wildlife habitat disturbances, new roads, ground disturbance, impact on historical properties, higher inconsistency with designated Recreation Opportunity Spectrum, and lower contributions to employment trends. Further, the 2021 MMP Alternative will likely: impact roadless characteristics in three inventories roadless areas; increase non-native plant species spread; and create construction noise into the Frank Church River of No Return Wilderness. As the proposed mine access routes (Burntlog Route and the Johnson Creek Route Alternative) are the primary difference between the two Action Alternatives, EPA recommends the FEIS clearly and sharply define issues related to each access route and ensure the assessments are accurately reflected across the different sections.</p>	ALT	SDEIS Section 2.7 describes the identification of the 2021 MMP as the Agency Preferred Alternative over the Johnson Creek Route Alternative. This identification does not conclude that the MMP 2021 does not have effects on resources but notes that it has lesser effects with regard to geological hazards, avalanches, spills, sedimentation, disturbance of riparian areas, timber resources, public safety, and tribal fisheries. Those lesser effects form the basis for the identification of the preferred alternative.
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	63	<p>Agency Preferred Alternative</p> <p>Rationale of 2021 MMP Identification</p> <p>The Executive Summary highlights three reasons the Forest Service identified the 2021 MMP Alternative as the Agency Preferred Alternative, but the first two bullets (i.e., incorporates water management and closure activities to reduce the duration of long-term water treatment requirements and</p>	ALT	The text has been revised to highlight the specific elements of the 2021 MMP compared to the Johnson Creek Route Alternative.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>incorporate measures to manage stream temperatures) are also true for the Johnson Creek Alternative since the mining portion of the Action Alternatives are the same. Similarly, Section 2.7 highlights eight reasons the Forest Service identified the 2021 MMP as the Agency Preferred Alternative, but the first two are also true for Johnson Creek Alternative. For the FEIS, since the Action Alternatives differ by proposed mine access routes, EPA recommends replacing these first two reasons with other primary reasons that are exclusive for the 2021 MMP.</p> <p>The Agency Preferred Alternative sections in the Executive Summary and Chapter 2, as presented, appear to imply that the Agency Preferred Alternative is environmentally superior to the Johnson Creek Alternative. For transparency, EPA recommends the FEIS provide additional context for the selection, such as if the reasons highlighted were given preference or prioritized over other potential negative impacts.</p>		
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	64	<p>Least Environmentally Damaging Alternative (LEDPA)</p> <p>Because the U.S. Army Corps of Engineers is planning to use this EIS to support its CWA Section 404 analysis, EPA recommends that the FEIS discuss whether the Agency Preferred Alternative is also the LEDPA.</p>	ALT	At the time of the SDEIS, the USACE had not determined its LEDPA.
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	65	<p>Environmentally Preferable Alternative</p> <p>EPA recommends the FEIS describe the criteria which will be used to ultimately determine the environmentally preferable alternative under NEPA.</p>	ALT	Edit has been made.
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	68	<p>Dry Stack Tailings</p> <ul style="list-style-type: none"> The DSEIS indicates the use of the dry stack method of tailings disposal was evaluated and determined to be technically and economically infeasible.68 An additional consideration in the determination to not fully evaluate a dry stack option is that stability of the proposed TSF is enhanced by the waste rock buttress so the stability advantage of a dry stack over a tailings impoundment is not as prominent for the SGP as it might be for other projects. We recommend that this consideration be included in the FEIS. 	ALT	Edit has been made.
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	69	<p>Agency Preferred Alternative</p> <ul style="list-style-type: none"> The rationale for Agency Preferred Alternative in Section 2.7 raises two travelway distances (i.e., 0.5 miles and 100ft) in comparison for potential spill contamination, sedimentation, and turbidity to streams during operations. <p>As there is very likely covariance (i.e., connection) between the two travelway distance zones and that these two zones could be repeating the same information, EPA suggests the FEIS use only one distance zone in this comparison.</p>	ALT	The text has been revised to make the travel way distances consistent.
Michael Gibson (Trout Unlimited), Aaron Lieberman (Idaho Outfitters & Guides Association), Garret Visser (Idaho Wildlife Federation)	18871	1	<p>The National Environmental Policy Act (NEPA) mandates that federal agencies "...Rigorously explore and objectively evaluate all reasonable alternatives..." 40 CFR §1502.14(a). However, the SDEIS only considers two Action Alternatives, both of which have the same actual mine plan. The range of alternatives analyzed in the SDEIS is simply inadequate given a project of this size, both environmentally and its social impact. The Forest Service should go back and develop an adequate range of alternatives in compliance with the mandates in NEPA. Additionally, the Forest Service should provide adequate justification for the elimination of other alternatives previously studied that had substantive differences in the mining portions.</p>	ALT	Section 2.6 of the SDEIS discusses 17 alternatives that were considered but were eliminated from further detailed analysis in the EIS for the reasons stated. New narrative has been added to Section 1.1 of the Final EIS explaining the handling of the action alternatives in the 2020 DEIS. CEQ has stated that "Reasonable alternatives include those that are practical or feasible from the technical and economic standpoint and using commonsense, rather than simply desirable from the standpoint of the applicant." (40 Most Asked Questions Concerning CEQs NEPA Regulations, Q/A 2a, 51 FR 15618, April 25,1986). CEQ has also stated, "an agency's responsibilities to examine alternatives sites has always been bounded by some notion of feasibility" and, "there is no need to disregard the applicant's purpose and needs and the commonsense realities of a given situation in the development of alternatives" (CEQ Guidance Regarding NEPA Regulations, 48 FR 34263, July 28, 1983). The 2021 MMP describes Perpetua's primary objectives based on professional examination of the mineral reserves, economics, and common sense (M3 2021). The 2021 MMP is based on economic and profitable production of the recoverable metal values, constrained by the site-specific physical conditions at the site such as geology, mineralization, topography, hydrology, and in

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
					this case, the legacy mining features. There is no need to disregard Perpetua's purpose and need for the Project and to develop alternatives that may be purely conjectural and whose implementation would be remote and speculative.
Zack Waterman (Northern Rockies Conservation Director)	19317	2	The SDEIS fails to consider a reasonable range of alternatives. The SDEIS only considers the applicant's proposed mine plan and a no-action alternative. This is not a reasonable range of alternatives. Please evaluate an alternative that utilizes underground mining operations rather than open-pit mining. Underground mining operations would greatly reduce the most adverse environmental impacts and must be considered. At a minimum, the Forest Service should consider a third alternative that significantly reduces adverse ecological impacts.	ALT	Section 2.6 of the SDEIS discusses 17 alternatives that were considered by were eliminated from further detailed analysis in the EIS for the reasons stated. These included underground mining and other alternatives that were considered. The action alternatives included in the SDEIS are considered to be sufficient for the evaluation of the 2021 MMP. There is no need to disregard Perpetua's purpose and need for the Project and to develop alternatives that may be purely conjectural and whose implementation would be remote and speculative.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	61	All the alternatives discussed in detail and dismissed would benefit from identifying which issues were considered when developing the alternatives. In particular, all the environmental design features and mitigation measures would be enhanced by including the significant issue.	ALT	Adding which issues were attached to each alternative considered but not evaluated, and each EDF or mitigation measure in the SDEIS would add unnecessary complexity to the narrative that is not required.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	62	" <i>Alternatives Screening Criteria</i> " - Most of the "significant issues" listed in 1.10 are addressed through the development of the environmental design features, agency mitigation measures, and Stibnite Gold mitigation measure. These are key and major components of the alternative development that we recommend be described briefly here.	ALT	Adding which issues were attached to each alternative, and each EDF or mitigation measure in the SDEIS would add unnecessary complexity to the narrative that is not required. Section 2.2 of the SDEIS adequately describes the process for identifying action alternatives.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	63	" <i>Options not meeting the purpose and need (Section 1.6) were documented and eliminated first</i> " Please describe which options do not meet the purpose and need. They are not described in the cited Section 1.6 as the citation indicates.	ALT	As described in the third complete paragraph of Section 2.2.2 of the SDEIS, component options are discussed in more detail in Section 2.6.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	65	" <i>A road maintenance facility</i> " - Recommend clarifying that the location of the maintenance facility is different between the alternatives, as reflected in Table 2.2-1.	ALT	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	66	" <i>Under the No Action Alternative, the Plan would not be approved and no mining, ore processing, or related activities would occur, including removal of legacy materials (i.e., SODA and Hecla heap leach) included in the Plan.</i> " Please insert after " heap leach ": " restoration of stream channels, and enhanced riparian plantings " included in the plan.	ALT	The recommended edit has not been made because Phase 1 of the ASAOC, which would occur if the No Action Alternative were selected does include some stream channel and riparian vegetation restoration.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	82	Recommend revising and clarifying this section by: 1) including a tie to why this alternative arose (public suggestion or which significant issue) and 2) consistently applying the rationale stated as to whether the alternative is not reasonable or does not meet the purpose and need (and why it doesn't meet the purpose and need).	ALT	The recommended clarifications in Section 2.6 have been added for the source of the alternatives discussed in Section 2.6 and why they may not be reasonable, or do not meet the purpose and need.
Alan Haslam (Vice President, Permitting,	19325	25	Recommend that the Agency Preferred Alternative should also cite improved fish access and habitat, consistent with our comments in Sections 3 and 4 of the SDEIS as well as the Specialist Report.	ALT	The principal differentiation between the alternatives regarding fish access and habitat is the reduced risk of traffic incidents and spills under the 2021 MMP. This reason for identification

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Perpetua Resources Idaho, Inc.)					of the 2021 MMP as the Preferred Alternative is already captured in the identification rationale.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	4	Accurate representation of the alternatives - including the No Action Alternative - is fundamental to reliable and defensible impact analysis for the comparison of alternatives. Thus, comments on Chapter 2 provide clarifying information or recommendations to improve the technical accuracy of the descriptions of activities and actions associated with each of the alternatives.	ALT	Noted. The specific comments included in this comment letter are responded to in other comments/responses for this and other comment categories. No further response is required here. General in nature or position statement.
Jon Robison	19330	8	An engineered stream underlain by a liner and displaced from the nearest stream reach by 400 vertical feet does not seem like a restoration project to me. The Forest Service should examine additional alternatives such as utilizing dry stack tailings to avoid these impacts.	ALT	Dry stack tailings disposal was considered and eliminated from detailed analysis for the reasons discussed in Section 2.6.2.2.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	197	Regarding the Johnson Creek Road, the SDEIS claims in numerous locations (see table 4.16-3, p. 4-491 of the SDEIS as an example) that once the Burntlog Route is complete, no mine traffic, and particularly heavy vehicles, will use the Johnson Creek route. We believe it is unreasonable to expect that zero mine traffic will use this route given the SDEIS fails to offer mitigation or Design Features that will ensure all mine traffic will adhere to the Burntlog Route. Further, Perpetua has stated the value of having redundant routes available in case of an emergency (DAC, 2021 at 1). Construction of the SGP under the Johnson Creek Road alternative is anticipated to extend the life of the project by two years. However, by not having to completely reclaim the Burntlog Route and the additional associated access roads/routes following closure, Perpetua may be faced with a null benefits/loss statement that in effect balances itself regarding fiscal output and total commitment. We recommend that the Forest Service complete a thorough cost/benefit analysis of these two alternatives to determine the true worth and value of each regarding potential impacts and adverse effects.	ALT	Section 2.4.4.3 of the SDEIS states that once the Burntlog Route is constructed it would be the primary SGP access and the Johnson Creek Road would no longer be used for mine-related traffic. The Johnson Creek Road would continue to be used as a public access road during the SGP construction and operations. Perpetua has proposed the Burntlog Route because it would avoid safety risks inherent with the Johnson Creek Road. There is no need to disregard Perpetua's purpose and need for the Project and to develop alternatives that may be purely conjectural and whose implementation would be remote and speculative.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	202	12. Use of an "upper slope" road is better than a "lower slope" road The gist of the argument in the DEIS (2020) and SDEIS is that the Johnson Creek/Stibnite road access ("lower road") will be worse than the Burntlog Route ("upper" or "mid-slope" road) access primarily from the number of landslides/rockslides, the extra two years of construction required if the Stibnite road is to be the primary haul route during construction, and the longer lengths of roads parallel to a stream. Literature shows that the lower roads "receive" the slides/rockfalls, but the upper/mid-slope roads generally "create" them. Many sediment creating and delivering functions exist in the literature on upper/mid-slope roads that have not been put into context to allow choices to be made between alternatives.	ALT	The specific comments included in this comment letter are responded to in other comments/responses for this and other comment categories. No further response is required here. General in nature or position statement.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	206	15. SDEIS contains two locations for the proposed Burntlog Maintenance Facility Two sites appear in various SDEIS, DEIS and Specialist documents to be the location of the proposed Burntlog Maintenance Facility site. One is adjacent to Peanut Creek, and the other at "...approximately 4.4 miles east of the junction of Johnson Creek Road (CR 10-413) and Warm Lake Road (CR 10-579)." These two sites are 0.5 miles away from each other and are physically different locations. If the two locations are presented as a form of "alternative," it is not clear which location is preferred, nor is it clear why the Forest Service/Perpetua would propose alternative locations for the same facility. In any event, we recommend that the Forest Service determine which location is accurate and remove all references to the second locale and complete data analysis, particularly those associated with sediment deposition, impacts to IRAs and wilderness, fisheries, and wildlife. We pose numerous questions and make recommendations regarding this specific topic in Newberry 2022 (Section 11.a.1, p. 19).	ALT	The location of the maintenance facility is associated with the selection of the access route. Under the 2021 MMP, the Burntlog Route would be the access route and the "Burntlog Maintenance Facility" would be located near the start of that route. Under the Johnson Creek Route alternative, the "Landmark Maintenance Facility" would be located near the junction of Johnson Creek Road and Warm Lake Road. Therefore, the location of the maintenance facility is a component of the access route selection.
Bonnie Gestring (Northwest Program Director,	17634	261	8. The SDEIS should include an action alternative that minimizes impacts eligible, suitable, and designated WSR values	ALT	As described in Section 3.23.4.2 of the SDEIS, the SGP would intersect with eligible or suitable WSR corridors at the proposed access roads and utility corridors, specifically, SFSR, Burntlog Creek, and Johnson Creek. Effects to the WSR values of these streams from the SGP are described in Section 4.23.2.2 of the EIS. As stated in Sections 1.10.3.4 and 4.23.2 there would not be any adverse effects that would affect the eligible segment and there would be no

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Earthworks) and seven others			All action alternatives in the SDEIS may harm WSR values besides the No Action Alternative. Another action alternative should be included in the FEIS and before the ROD that eliminates harm to the eligible, suitable, and designated WSR values in case the project moves forward.		impairment to the free-flowing characteristics of the segment. Therefore, the Project would comply with FSH 1909.12, Chapter 84.3.
David Chambers	17634-A	1	The Stibnite Gold Project Supplemental Draft Environmental Impact Statement (SDEIS) analyzes one open pit mining project proposal, with two access road alternatives. There are no mining alternatives analyzed. Underground mining had been eliminated from evaluation in the DEIS on the basis that underground mining is not economic, but this rationale is supported only by innuendo, not by technically defensible information. Because the potential for underground mining is heavily promoted by Perpetua in its feasibility studies, this mining alternative should have been included for more detailed analysis.	ALT	<p>Underground mining practices were common in the past but have largely been replaced by open pit mining due to efficiencies of scale provided by improvements in mining equipment and methods. Underground mining is still conducted worldwide but has been shown to only be practical when the target ore body is too deep to mine profitably by open pit and the ore grades are high enough to cover costs. The history of the Stibnite property is an example of this economic transition. The earlier mining activities at Stibnite were underground but later mining operations were all of the open pit type.</p> <p>The 2021 feasibility report only describes open pit operations for the proposed target orebodies. If underground mining of these orebodies was technically and economically feasible, the experts involved with the NI-43-101 Feasibility Report would have most likely discussed it. It can therefore be concluded that applying underground mining methods to development of the orebodies included in the 2021 MMP would not be financially feasible or comply with the purpose and need for the project.</p> <p>If the same orebodies were to be developed by underground methods, other aspects of the project would not be feasible. The amount of development rock removed from the underground workings would be much less than is proposed in the 2021 MMP. This would provide less material for backfilling the Yellow Pine pit and to buttress the TSF embankment.</p> <p>The 2021 feasibility report does discuss the presence of potential, future underground mine targets for other, higher-grade orebodies within the SGP property. The report is clear that current exploration information of potential underground targets is insufficient and additional exploration of these targets is necessary before providing the required information on ore grades, continuity, scale, and geotechnical characteristics required to define a mineral resource. Therefore, future underground mining operations at the SGP is currently too speculative for evaluation under NEPA.</p> <p>There is no need to disregard Perpetua's purpose and need for the Project and to develop alternatives that may be purely conjectural and whose implementation would be remote and speculative.</p>
David Chambers	17634-A	4	<p>2.2 Development of Alternatives</p> <p>From a mining perspective, there is only one alternative analyzed in the SDEIS – the 2021 MMP as proposed by Perpetua. The alternatives consist of two different access road options to the mine. As discussed further in Section 2.6.1.1 below, there are several good reasons for an underground mine alternative to be analyzed, and the EIS analysis has not conclusively demonstrated that underground mining is not economically viable. Hand waving arguments about a lack of economic viability do not provide sufficient justification to eliminate an alternative that could provide a significant reduction in environmental effects.</p> <p>As now presented, there is no real alternative to the mining project proposed by Perpetua, in spite of the fact that the company proposes an extensive underground drilling prospect as a part of this project proposal, and has promoted several possible underground prospects to potential investors as a part of its most recent Feasibility Study (M3 2021).</p> <p>The potential for underground mining should be viewed first in the light of a choice as an environmentally preferable SDEIS alternative. Underground mining would mean less waste disposal on the surface, and less disruption of existing surface water flows, while still allowing removal of the existing source of contamination proposed for the open pit mining alternative. In the haste to eliminate underground mining as a consideration, a potential environmentally preferable option is not being properly analyzed.</p>	ALT	<p>Underground mining practices were common in the past but have largely been replaced by open pit mining due to efficiencies of scale provided by improvements in mining equipment and methods. Underground mining is still conducted worldwide but has been shown to only be practical when the target ore body is too deep to mine profitably by open pit and the ore grades are high enough to cover costs. 					<p>The 2021 feasibility report does discuss the presence of potential, future underground mine targets for other, higher-grade orebodies within the SGP property. The report is clear that current exploration information of potential underground targets is insufficient and additional exploration of these targets is necessary before providing the required information on ore grades, continuity, scale, and geotechnical characteristics required to define a mineral resource. Therefore, future underground mining operations at the SGP is currently too speculative for evaluation under NEPA.</p> <p>There is no need to disregard Perpetua's purpose and need for the Project and to develop alternatives that may be purely conjectural and whose implementation would be remote and speculative.</p>
David Chambers	17634-A	10	<p>2.6 Alternatives Considered but Eliminated from Further Detailed Study - 2.6.1.1 Underground Mining</p> <p>The SDEIS does not provide adequate justification for eliminating underground mining as an alternative to be considered in the SDEIS. In explaining why underground mining was eliminated as a consideration in the SDEIS, the rationale presented begins by asserting:</p> <p>“In aggregate, grades for these three deposits above a 0.48 grams per ton (g/t) gold cut-off grade averaged 1.43 g/t gold, 1.91 g/t silver, and 0.064 percent antimony (M3 2021). Typical economic cutoff grades for underground mine operations are approximately 5 g/t gold.” (SDEIS 2022, emphasis added)</p> <p>The basic consideration for potential economic viability must begin by considering how much gold greater than the cutoff grade that has been identified, and whether this amount would justify underground mining. This is not addressed in the SDEIS analysis.</p> <p>In addition, if underground mining were to take place, the cutoff grade would likely be less than the 5 g/t proposed in the SDEIS. The reference cited in the SDEIS, the Stibnite Gold Project Feasibility Study (M3 2021), has an entire section devoted to the discussion of “Potential high-grade underground exploration prospects” (M3 2021, Section 9.8). In that section M3 using “gold cutoff” values of 2.4 g/t and 3 g/t, both of which are well below the 5 g/t cited in the SDEIS. The SDEIS does not give a citation for its choice of 5 g/t as “Typical economic cutoff grades for underground mining ...”. The 5 g/t cutoff grade is not mentioned in the Feasibility Study. The choice of a typical cutoff grade for underground mining in the SDEIS should at least be consistent with the information being presented to the company’s potential investors in its technical reports.</p> <p>Unlike the Feasibility Study, which aggressively addressed the possibility for underground mining to potential investors, the SDEIS appears to avoid serious discussion of underground mining as a possibility by proposing underground mining is economically unfeasible, then failing to defend that premise with any quantitative analyses.</p> <p>The potential for underground mining should also be viewed in the light of a potential choice as an environmentally preferable SDEIS alternative. Underground mining would mean less waste disposal on the surface, and less disruption of existing surface water flows, while still allowing removal of much of the existing waste sources of contamination proposed for the open pit mining alternative. In the haste to eliminate underground mining as a consideration, a potential environmentally preferable option is not being properly analyzed.</p>	ALT	<p>Underground mining practices were common in the past but have largely been replaced by open pit mining due to efficiencies of scale provided by improvements in mining equipment and methods. 			<p>quantity, fisheries, special status fish species, and other resources. The Forest Service should prepare a new or supplemental EIS to consider additional alternatives, that would result in less substantial environmental harm, while still meeting the Forest Service's obligation to consider the SGP plan of operations and allow access to the public lands to search for minerals, including the alternatives described below.</p> <ul style="list-style-type: none"> - All four of the action alternatives will have negative impacts across an affected area ranging between 3,219 acres and 3,533 acres. The Forest Service should analyze alternatives that limit the footprint of development to a smaller total acreage, including an alternative that limits the mine footprint to previously disturbed areas. - The FS should analyze an alternative that is similar to the no action alternative, but that includes removal of the Soda and Brady tailings to restore fish habitat. - The Forest Service should consider an action alternative that is consistent with the Payette and Boise Land and Resource Management Plans, and that does not require that the plans be amended. - The Forest Service should analyze an alternative that includes more effective measures to avoid, minimize and mitigate adverse impacts water quantity and quality and fish populations, particularly endangered fish species. This should include an alternative that results in a net improvement in water quantity, water quality, and the health of fish populations and riparian ecosystems in the Salmon River and its tributaries. - The Forest Service should analyze an alternative that proposes mineral withdrawal for the Salmon River watershed (while this would ultimately require congressional action, it is appropriate for the Forest Service to analyze an alternative that protects the world class resources in the watershed (including the health of the Salmon River and its tributaries, wetlands and riparian areas, roadless areas, wildlife, scenic values, etc.) from mining. - The Forest Service should analyze an alternative that avoids building roads, allowing surface disturbance, and putting mining waste in undisturbed habitat for fish species, particularly endangered fish species. In addition, the FS should analyze an alternative that prohibits activities likely to result in contamination of streams with arsenic, methylated mercury, and other minerals and compounds likely to cause significant long-term adverse impacts on fish species, particularly endangered fish species. - The Forest Service should analyze an alternative that reconnects fish habitat, isolates historic mine waste from streams, and restores degraded riparian areas. <p>I urge the FS to prepare a new or supplemental DEIS which includes consideration of a broader range of alternatives.</p>		<p>mining and other alternatives that were considered. The action alternatives included in the SDEIS are considered to be sufficient for the evaluation of the 2021 MMP. The Forest Service's choice of action alternatives can be influenced by the primary objectives of the 2021 MMP. There is no need to disregard Perpetua's purpose and need for the Project and to develop alternatives that may be purely conjectural and whose implementation would be remote and speculative.</p>
Samuel Penney (Chairman)	19396	25	<p>2.2 Inadequate Range of Alternatives Nez Perce Treaty Rights Alternative</p> <p>As part of the purpose and need, the SDEIS identifies as one of the needs to "[e]nsure that the proposed occupancy and use of NFS lands is consistent with statutory and regulatory requirements." The 1855 Treaty, as the Supreme Law of the Land under the United States Constitution, is identified in the SDEIS as an applicable federal law to which compliance is required to meet the Project's purpose. The Forest must develop and include in the SDEIS all reasonable alternatives that protect Nez Perce treaty rights and resources. In fact, the Proposed Action and neither alternative in the SDEIS fulfill these requirements. The Forest concluded in the SDEIS that the Project will substantially and irreparably harm treaty rights and resources and cultural resources under both action alternatives. Construction and operation of the mine would directly and indirectly cause major harm to tribal resources. Tribal access to areas within the Project would be restricted during the Project's construction, operation, and closure and reclamation phases, preventing Nez Perce tribal members from exercising off-reservation rights to fish, hunt, gather, and pasture, for a period of 20 years, excluding reclamation. The Project would also impact salmon and other aquatic species and essential fish habitat that would in turn impact availability and</p>	ALT	<p>SDEIS Section 2.2.2 describes the alternatives development process. Potential alternatives were screened based upon four criteria: does it meet the purpose and need; does it reduce environmental effects to at least one resource; is it technically feasible; and is it economically feasible. Alternatives not meeting the purpose and need were the first ones eliminated. The remaining ones were then evaluated for technical and economic feasibility and potential environmental impacts using the significant impact issues identified during scoping, which included impacts to Tribal Treaty Rights (Section 1.10 SDEIS).</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			harvestability of these and other treaty-reserved resources by the Tribe at its traditional fishing, hunting, and gathering areas. Given the Forest's treaty--based duty to avoid taking action resulting in harm to the Tribe's treaty rights, the Forest's two alternatives in the SDEIS are unreasonably narrow because both result in substantial and irreparable harm to the Tribe's treaty rights and resources.		
Samuel Penney (Chairman)	19396	26	<p>No Forest Plan Amendments Alternative</p> <p>The SDEIS states: "When a proposed project is not consistent with Forest Plan standards applicable to the location of a project and/or the types of activities proposed, the Forest has the following options: (1) modify the proposed project to make it consistent with the Forest Plan; (2) reject the proposal; (3) amend the Forest Plan so that the project would be consistent with the Forest Plan as amended; or (4) amend the Forest Plan contemporaneously with the approval of the project so the project would be consistent with the Forest Plan as amended."</p> <p>The Forest's discretion to exercise any of these options to achieve Forest Plan consistency is not unbounded. The Agency's action is expressly "subject to valid existing rights." There is no question that the Tribe's rights reserved in its 1855 Treaty with the United States are "valid existing rights" applicable to the Project area. These rights constrain the Forest's discretion to amend existing Forest Plan standards in ways aimed at accommodating the Project but which are inconsistent with the Agency's treaty-based and trust obligations to the Tribe and will result in harm to the Tribe's treaty-reserved rights and resources. Such is the case here. For example, the Forest seeks to amend standards that will remove existing prohibitions on the degradation of aquatic, terrestrial, and watershed resource conditions from beyond three years. These standards, if amended, would authorize long-term degradation to resource conditions that will substantially and impermissibly harm the Tribe's treaty-reserved rights and resources.</p> <p>To avoid harm to the Tribe's treaty-reserved rights and resources while maintaining consistency with Forest Plan standards, the Forest should not use option three above that weaken Forest Plan standards that harm the Tribe's treaty resources. Instead, the Agency must include and rigorously explore new reasonable alternatives that protect the Tribe's rights by embracing option one (change the Project) or option two (reject the proposal) and which by their terms do not require Forest Plan amendments.</p>	ALT	The Forest Service would require modifications and mitigation measures to make the Project consistent with the Forest Plans to the extent practicable. In instances where consistency would not be achieved while meeting the Project's purpose and need, the Forest Plans would be amended at the same time as the Project ROD. Appendix A of the SDEIS is a review of Forest Plan consistency and proposed amendments as part of the Project. As part of the analysis and decision on this Project, the Forest Service explored modifications and measures protective of Tribal treaty resources.
Samuel Penney (Chairman)	19396	27	<p>Project Life Phases Alternative(s)</p> <p>As noted in the EIS Scoping and Issues Summary Report (Section 2.6.12 Alternatives Development, one recommendation was, "[f]or every phase of mine life, develop a series of alternatives in which the restoration components can be pursued without ongoing mine development activities." Mine life phases are generally recognized as exploration, permitting, construction, operations, reclamation and closure, and post-closure. Additionally, mine life phases may include different operations periods representing periods of mining, such as those involving mining of different open pits and other areas as described in the SDEIS. The SDEIS only includes alternatives that assume the mine is operated and closed as proposed and does not include alternatives that require restoration components without mining development, or for closure during mine life operational phases despite evidence of clear economic issues in later mine years.</p>	ALT	The 2021 MMP describes Perpetua's primary objectives based on professional examination of the mineral reserves, economics, and common sense. The SGP mine plan was designed to produce the target metals with an economically efficient operation. The Project mine plans are based on economic and profitable production of the recoverable metal values, constrained by the site-specific physical conditions at the site such as geology, mineralization, topography, hydrology, and in this case, the legacy mining features. There is no need to disregard Perpetua's purpose and need for the Project and to develop alternatives that may be purely conjectural and whose implementation would be remote and speculative.
Samuel Penney (Chairman)	19396	28	<p>No Antimony Production Alternative</p> <p>The U.S. Geological Survey produced a report on antimony that addresses its uses and applications; demand, availability of supply and consumption; strategic and critical resource issues; geology; resources and production; exploration for new deposits; environmental considerations; and problems and future research. The results are summarized as follows:</p> <p>Antimony is used widely by modern industrialized society. Antimony's leading use is as a fire retardant in safety equipment and in household goods, such as mattresses. The element imparts strength, hardness, and corrosion resistance to alloys, including in lead-acid storage batteries.</p> <p>The demand and availability of supply and consumption has increased during the past century from 7,710 metric tons in 1900 to 185,000 metric tons in 2008. In 2013, China produced about 80 percent of</p>	ALT	Table 17-3 of the 2021 Feasibility Report (M3 2021) shows that the higher antimony concentrations in the ore also occur along with the higher gold grades during the first years of the operations. The antimony grades then drop off to low concentrations in the later years of the operations, with the exception of year 9 where antimony concentrations are similar to the early years. The Feasibility Report states that the antimony flotation circuit would be operated to produce an antimony concentrate except for years of low-antimony mill feed when the ground ore would bypass the antimony flotation circuit and be processed in the gold/silver flotation circuit. Section 3.8.4 of the 2021 MMP also discusses this matter and states that 15 to 20 percent of the total mill feed is expected to have sufficient antimony grade to warrant removal of an antimony concentrate. The Antimony Flotation subsection of Section 2.4.5.7 of

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>the world's supply of antimony. In the United States, there is one active antimony smelter in Thompson Falls, Montana (United States Antimony Corp.). Apparent consumption of antimony by the United States from 1979 to 2009 has ranged from approximately 20,000 metric tons to 47,000 metric tons with the peak occurring in 1997 and lower demand occurring since 2009.</p> <p>The U.S. Government has considered antimony to be a critical mineral mainly because of its use in military applications. Currently, China has the bulk of the world's identified antimony resources, the majority of the world's antimony is mined in China, and much of the remainder is shipped to China for smelting. However, the U.S. Geological Survey report notes that, "[b]arring market manipulation by a few dominant producers, recycling, mining, and smelter production are expected to meet the demand for antimony and antimony compounds for the foreseeable future."</p> <p>There are abundant identified antimony resources available, but the bulk of those resources are in a few very large deposits that are not evenly distributed across the globe. Today's market favors large deposits that are conducive to high-volume bulk-mining techniques. The United States and the countries of the Western Hemisphere appear to have mostly small deposits that are uneconomic to mine under current and foreseeable conditions. According to the report the United States has no deposits, from which the ore is mined principally for antimony, that are large enough or rich enough to compete with foreign sources in normal times. The Perpetua proposed Project is cited as an example of identified resources in the United States that meet this description.</p> <p>The U.S. Geological Survey report notes that, "[a]ntimony resources that may be mined in the future are likely to be those tied directly to deposits of precious metals, copper, lead, and (or) zinc, similar to those from which most domestic antimony has historically been recovered as a byproduct or coproduct. Gold is an important joint product with antimony, but gold-antimony veins are commonly mined just for their gold. Because the presence of antimony makes gold more difficult and more expensive to process (the antimony interferes with the heap-leaching agent by consuming oxygen and hindering the effect of cyanide on the gold ore), some amount of gold ore that has a high antimony grade may be stockpiled." The report goes on to note that "[e]nhanced recovery of antimony from precious-metal deposits may represent the most readily available source of antimony if demand were to increase rapidly" and that antimony could be recovered from existing mines in Idaho and Nevada.</p> <p>Information on antimony mine waste related to the environment is extremely limited. Limited data are available on the acid-generating potential of antimony mineral bearing mine waste. The presence of carbonate minerals, such as calcite, and only minor amounts of pyrite in the mine waste from antimony deposits in general suggest that the acid-neutralizing potential is likely to exceed the acid-generating potential of the mine wastes.</p> <p>In general, trivalent antimony (Sb³⁺) is more toxic than pentavalent antimony (Sb⁵⁺). In humans, antimony can result in diseases of the liver, respiratory and cardiovascular systems, and skin. Compared to trivalent arsenic, pentavalent antimony is 5 times less cytotoxic and 10 times less genotoxic. The EPA has set a maximum contaminant limit of 6 ppb for antimony and 10 ppb for arsenic for drinking water. The World Health Organization drinking water guideline is 20 ppb for antimony and 10 ppb for arsenic. National ambient-water-quality criteria with respect to freshwater organisms are not available from the EPA for antimony; however, mine drainage from antimony mines can locally exceed both acute and chronic ecological guidelines for antimony and arsenic.</p> <p>The report notes that from an environmental perspective, no clear case study of the behavior of antimony and related trace elements in a modern mine setting using current best practices exists. The toxicity of aqueous antimony species to aquatic organisms is a notable gap in knowledge. Knowledge of the toxicity of antimony in sediments is also limited.</p> <p>The Stibnite Mine was named for the antimony containing sulfide mineral stibnite (Sb₂S₃). As noted in the PRO, the Project area was historically mined from the mid-1920's through 1952 for antimony, gold, and tungsten using both underground and open pit mining methods, and from 1982 to 1997 for gold using open pit methods. The mining, milling and processing activities created numerous legacy impacts including underground mine workings, multiple open pits, development rock dumps, tailings deposits,</p>		<p>the SDEIS states that ore high in antimony would be processed by the antimony flotation circuit to produce an antimony concentrate.</p> <p>The Antimony Concentrate Transport subsection of Section 2.4.5.7 of the SDEIS describes that the antimony concentrate would be placed into supersack containers at the mill which would then be placed within shipping containers that would be fully enclosed for truck transport offsite. One to two truckloads of concentrate are described to be shipped daily when the concentrate is being produced. So significant storage of antimony concentrate on site is not expected. Temporary storage of the individual shipping containers at offsite terminals or ports is no different than the current operations of those facilities so incremental environmental effects from the same are not expected.</p> <p>So not producing an antimony concentrate in the low antimony feedstock years is already part of the 2021 MMP. When an antimony concentrate is being produced, the tailings from the antimony flotation circuit would continue on to the gold/silver flotation process. Operation of the antimony flotation circuit would have minimal impact on the amount of tailings being sent to the TSF, the only difference being the small percentage of ore being removed as antimony concentrate. Because the antimony mineralization occurs along with the gold/silver mineralization, the same amount and type of ore and development rock would still be removed from the open pits whether or not an antimony concentrate is produced. Because this aspect of not producing antimony concentrate in certain years of the operations has already been incorporated into the 2021 MMP and the environmental analyses, there is no need to consider a separate alternative.</p>

			<p>heap leach pads, spent heap leach ore piles, a mill and smelter site, three town sites, camp sites, a ruptured water dam (with its associated erosion and downstream sedimentation), haul roads, an abandoned water diversion tunnel, an airstrip and other disturbance.</p> <p>The proposed process circuit for the Project includes crushing, grinding, flotation, pressure oxidation and cyanide leaching. The flotation circuit consists of up to two sequential flotation stages to produce two different concentrates; the first stage of the circuit was designed to produce an antimony-rich concentrate, and the second stage was designed to produce a gold-rich concentrate that is pressure oxidized and cyanide leached for the recovery of gold and silver. If the antimony content of the feed material is not present in economic concentrations, then the antimony circuit would be bypassed and a gold bearing sulfide concentrate would be the only concentrate produced by the flotation circuit.</p> <p>The December 22, 2020 Stibnite Gold Project Feasibility Study Technical Report (“Feasibility Report”) is based on producing a by-product antimony concentrate with sale of the concentrate to an antimony smelter, with the report noting that “suitable, currently operating antimony smelters are located in Asia or Oman” Smelters use a combination of pyrometallurgical processes to produce antimony metal including roasting to remove sulfur, fuming to produce antimony oxide, and reduction to produce antimony metal. The shipment of concentrate to an overseas smelter was considered appropriate given the estimated cost and perceived complexity of building and operating a secondary antimony processing plant.</p> <p>ModPro2 acknowledges this in the following passage: “The concentrate, when sold, would likely be shipped to facilities outside of the United States for smelting and refining because there are currently no such facilities operating in the United States with capacity for refining antimony sulfide concentrate. There are United States companies with refining equipment facilities and expertise that could potentially be brought online at some future date to refine antimony sulfide concentrate; however, Perpetua Resources does not have contracts in place with these companies and their ability to handle these concentrates has not been determined.”</p> <p>The importance of antimony as a matter of Project economics is overstated. As shown in Table 1 from the Feasibility Report base case, the gross revenue from the production of antimony is only expected to earn \$275M over the Project life, or less than 4% of total revenue, while gold is expected to earn \$6.7B over the Project life, or 96% of total revenue. In addition, the cost of further shipping and refining gold is by orders of magnitude less than what is anticipated for antimony, making the net impact on Project economics even less significant. This suggests that there are multiple factors making antimony production economics from the Project marginal, and potentially revenue negative.</p> <p>Table 1. Stibnite Gold Project Feasibility Report (TABLE)</p> <p>The aspect of antimony as a strategic and critical mineral has been over-emphasized with respect to the proposed Project. Recovery of antimony from precious-metal deposits currently being mined in Nevada and elsewhere in the United States represent a readily available source of antimony, if domestic production was considered justifiable. The more critical issue regardless of source would be antimony smelting capacity, which is currently limited. Present plans to ship antimony concentrates to China for smelting would in fact only do more to compound any present strategic or critical mineral issues.</p> <p>The matter of antimony production from the Project is primarily a matter of economics. If the proposed Project proceeds to production, and economics do not warrant antimony production, it is not assured that antimony production will be included as part of the process, or as an Alternative that it will continue to be operated throughout the Project life. Given that a change in the proposal to not produce antimony in the future might have a significant impact on tailings and even possibly waste rock geochemistry, this option should have been considered as an Alternative in the SDEIS.</p> <p>The SDEIS should also address the potential for antimony production to not occur at any point in the project life cycle. The SDEIS should include this as an action alternative and modify the environmental analysis to address what additional impacts would be expected should this occur in terms of the overall</p>		

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			resource mined and/or milled, waste rock and tailings quantities and geochemistry, and impacts to water quantity and quality. If it is not included as an alternative, then the SDEIS should address what regulations would have to be addressed and how or if mining operations would be allowed to proceed until regulatory approvals are received. The SDEIS should also address limitations of the amount of concentrate stored at the site or otherwise stockpiled at locations outside of the mine site in the event the antimony is not immediately sold for refining.		
Samuel Penney (Chairman)	19396	29	<p>Early Closure</p> <p>As shown in Figure 1.5 Mill Feed and Gold Head Grade by Deposit and Year in the Stibnite Gold Project Feasibility Report as referenced in the SDEIS, gold production peaks in year four of the project life and then significantly declines over the remaining project life. Given the volatility of gold prices, as well as uncertainty in silver prices and the antimony market overall, there is a reasonable possibility of early closure of the proposed project. The SDEIS should include as an action alternative the possibility of early closure and address what impacts and mitigation specific to that action would occur. The SDEIS should address if this would occur, how long operations could be suspended before the mine would be required to undergo permanent closure.</p>	ALT	It is the Forest Service's intention that the permanent closure characteristics described in Section 2.4.7 of the SDEIS would be achieved. Temporary closure of the operations is included in Section 2.4.5.15 of the SDEIS. This section describes what actions would continue during a temporary closure of the facilities to maintain compliance with commitments for monitoring and environmental compliance. It also states that compliance with the proposed permanent regulatory closure characteristics would be required, unless modified by the required regulatory authorities. The 2021 Feasibility Report (M3 2021) describes the economic risk analysis for the Project as designed and utilizes a base case gold price of \$1,600/oz. using the 3-year trailing price (60%) and the 2-year futures price (40%). The gold price in the last three years has ranged from about \$1,650/oz. to over \$1,900/oz. The economic analysis for the SGP utilized five metal price cases for gold from a low of \$1,350/oz. to a high of \$2,350 oz. At the low price point for gold, the payback period for the Project was less than 4 years and the internal rate of return before taxes was just over 17%. The situation described in the comment that gold and silver pricing could drop in the future to a point where continued mining at the SGP would be terminated early is considered to be unlikely and not foreseeable. It is considered more likely that the entire Project would be completed through final reclamation as described in the 2021 MMP. There is no need to disregard Perpetua's purpose and need for the Project and to develop alternatives that may be purely conjectural and whose implementation would be remote and speculative.
Samuel Penney (Chairman)	19396	30	<p>Alternatives Considered, Carried Forward, or Eliminated from Further Study Section 2.6 of the SDEIS frequently cites various alternatives in this section as not being either "technically feasible" and/or "economically feasible." However, nowhere in the SDEIS are these terms defined. Similarly, the basis for the alternatives provided in AECOM 2020 does not define technical or economic feasibility. Stibnite Gold Project EIS Draft Alternatives Considered, Carried Forward, or Eliminated from Further Study does however note that "In determining the range of alternatives to be considered, the emphasis is on what is "reasonable" rather than on whether the proponent or applicant likes or is itself capable of carrying out a particular alternative. Reasonable alternatives include those that are practical or feasible from the technical and economic standpoint and using common sense, rather than simply desirable from the standpoint of the applicant." This desire of the applicant is nonetheless indicated as influencing the decisions as suggested that "Information also was solicited from Midas Gold regarding the technical and economic feasibility of alternatives." Perpetua's input as the basis for technical or economic feasibility should not have been used as the basis for the Project SDEIS, however lacking further definitions, and analysis and consideration of the alternatives relative to those definitions, it would appear the SDEIS relies entirely on Perpetua's input.</p>	ALT	CEQ has stated that "Reasonable alternatives include those that are practical or feasible from the technical and economic standpoint and using commons sense, rather than simply desirable from the standpoint of the applicant." (40 Most Asked Questions Concerning CEQs NEPA Regulations, Q/A 2a, 51 FR 15618, April 25,1986). CEQ has also stated, "an agency's responsibilities to examine alternatives sites has always been bounded by some notion of feasibility" and, "there is no need to disregard the applicant's purpose and needs and the common sense realities of a given situation in the development of alternatives" (CEQ Guidance Regarding NEPA Regulations, 48 FR 34263, July 28, 1983). The 2021 MMP describes Perpetua's primary objectives based on professional examination of the mineral reserves, economics, and common sense (M3 2021). The 2021 MMP is based on economic and profitable production of the recoverable metal values, constrained by the site-specific physical conditions at the site such as geology, mineralization, topography, hydrology, and in this case, the legacy mining features. There is no need to disregard Perpetua's purpose and need for the Project and to develop alternatives that may be purely conjectural and whose implementation would be remote and speculative.
Samuel Penney (Chairman)	19396	31	<p>For an alternative to be economically feasible, the standard should not be whether the alternative retains the present projected profitability, but instead what is practical or reasonable. The following figure (Chart 3) shows the rate of return for the United States domestic mining industry as well as other industry groups for the period 1999-2018. As suggested by the figure, none other than nondurable-goods manufacturing have consistently achieved a rate or return of 19.3%, and the mining industry's rate or return has ranged from less than zero to a high of below 10%. Therefore, it might be reasonable for an alternative to be economical provided the proponent achieves a rate of return of 10%. This would then be the standard upon which to measure the economic feasibility of a given alternative. By performing a cash flow analysis similar to that contained in the prefeasibility study but adding capital and operating costs, an evaluation can be made as to actual potential economic impacts.</p>	ALT	CEQ has stated that "Reasonable alternatives include those that are practical or feasible from the technical and economic standpoint and using commons sense, rather than simply desirable from the standpoint of the applicant." (40 Most Asked Questions Concerning CEQs NEPA Regulations, Q/A 2a, 51 FR 15618, April 25,1986). CEQ has also stated, "an agency's responsibilities to examine alternatives sites has always been bounded by some notion of feasibility" and, "there is no need to disregard the applicant's purpose and needs and the common sense realities of a given situation in the development of alternatives" (CEQ Guidance Regarding NEPA Regulations, 48 FR 34263, July 28, 1983). The 2021 MMP mine plan describes Perpetua's primary objectives based on professional examination of the mineral reserves, economics, and common sense (M3 2021). The 2021 MMP is based on economic and profitable production of the recoverable metal values, constrained by the site-specific physical conditions at the site such as geology, mineralization, topography, hydrology, and in

			The SDEIS and supporting AECOM 2020 Stibnite Gold Project EIS Draft Alternatives Considered, Carried Forward, or Eliminated from Further Study document should have provided a definition of technical and economic feasibility; and the rationale of each alternative with respect to technical and/or economic feasibility should have been evaluated and considered therein. The basis for economic feasibility should consider what is typical for the mining industry and a range of gold prices including the current gold price. Technical feasibility also should not be based on what Perpetua would prefer to do, but rather, what can be done.		this case, the legacy mining features. There is no need to disregard Perpetua's purpose and need for the Project and to develop alternatives that may be purely conjectural and whose implementation would be remote and speculative.
Samuel Penney (Chairman)	19396	32	<p>Section 2.6.2.2. Tailings Storage Facility (“TSF”) Dry Stack Tailings states, “The use of the dry stack method of tailings disposal was evaluated and determined to be technically and economically infeasible.” The determination as to the inclusion of dry stack tailings is based on AECOM 2020b which contains the following summary: “In AECOM’s professional opinion, filtered (dry stack) tailing is not feasible, both technically and economically, for the Project. This is due to the proposed fine tailing grind and filter clogging, the tailing transport, placement, and compaction issues resulting from the site’s wet and cold climate, an unprecedented tailing production rate for a filtered (dry stack) facility, and the relatively high operating costs discussed above. This opinion conflicts with other projects that have come to different conclusions, but where the project proponent ultimately favored the result. This includes not only the Greens Creek and Pogo Mines mentioned by AECOM, but also the Rosemont Project referenced by AECOM, as well as the Twin Metals project. Clearly, if filtered (aka dry stack) tailings are desirable, it can be achieved.</p> <p>Rather than subjectively address the technical and economic feasibility of dry stack tailings, the SDEIS instead should have addressed whether dry stack tailings would provide an environmental or safety advantage over the Alternatives examined in the SDEIS. Given the level of public interest and concern regarding potential tailings catastrophic failures, dry stack tailings should have been carried forward as an alternative for comparison with the other alternatives in the SDEIS.</p>	ALT	The AECOM evaluation of dry stack tailings is still applicable to the SGP. Additionally, dry stack tailings can be considered to offer greater stability from potential release of tailings water and solids from a TSF. All of these factors should be evaluated on a site-specific basis and the fact that dry stack tailings are used in other mining operations with different settings does not necessarily mean they should be applied to the SGP. Since the AECOM review was completed, Perpetua redesigned the TSF and TSF Buttress, as described in the 2021 MMP, to afford extraordinary support for the TSF embankment. As discussed in the Geotechnical Stability subsection of Section 4.2.2.2 of the SDEIS, the factor of safety of the revised design exceeds the regulatory requirements for long-term tailings storage.
Samuel Penney (Chairman)	19396	33	<p>2.3 No Action Alternative</p> <p>Inadequate Description of Baseline Conditions and No Action Alternative</p> <p>Under NEPA, the Forest is required to "describe the environment of the area(s) to be affected or created by the alternatives under consideration...." The establishment of the baseline conditions of the affected environment is a fundamental requirement of the NEPA process and is critical to any NEPA analysis. "Without establishing the baseline conditions which exist... before [a project begins, there is simply no way to determine what effect the [project] will have on the environment and, consequently, no way to comply with NEPA."</p> <p>The DEIS and SDEIS do not completely and accurately describe the no action alternative which the SDEIS uses as a baseline condition for comparing the environmental effects of the proposed action and alternatives. Other than a few obvious features such as the Yellow Pine pit, the DEIS and SDEIS do not identify or describe, or otherwise account for as baseline conditions, the numerous and significant discharges and sources of contamination existing at the present, nonremediated site.</p>	ALT	The affected environment is described in Chapter 3.0 of the EIS and is based on available information and site studies that provide a description of current conditions for the resources evaluated in the EIS. These descriptions include the existing effects of legacy mining features at the property. Chapter 3.0 details of the existing effects of legacy mining features on each of the discussed environmental resources are discussed. The scale of this discussion for each resource is relative to the issues being addressed. For example, the effect of legacy mining on surface waters is generally described in Section 3.8.4.2 of the SDEIS. The surface water quality monitoring locations along the streams in the Project area are described in the section. The surface water quality data from the monitoring locations are described in Section 3.9. A description of the chemical influence of historical mining wastes is located in Section 3.9.4.3. This captures the overall chemical effects of the legacy mining features on the streams which is more relevant than individual contributions from discrete legacy mining features like tunnels.
Samuel Penney (Chairman)	19396	40	The SDEIS fails to recognize that the restoration of the mine site without additional mining would be expected to result in a significant improvement to existing water quality conditions as compared to baseline conditions described in the SDEIS. The SDEIS should have described the existing conditions in detail with respect to legacy mining activities and their impact on water quality, and used restored rather than existing conditions to establish and compare as baseline conditions for all other alternatives considered in the SDEIS.	ALT	The affected environment is described in Chapter 3.0 of the EIS and is based on available information and site studies that provide a description of current conditions for the resources evaluated in the EIS. These descriptions include the existing effects of legacy mining features at the property. As described in the following comment response, the only reasonably foreseeable cleanup response that can be considered for the No Action Alternative is the Phase 1 work included in the ASAOC. The ASAOC scope of work for these response activities does not include prediction of the environmental effects of the work. Description of these effects are not yet available and would be learned from future monitoring after the Phase 1 work was completed by 2025. The subsequent phases described in the ASAOC are optional and could be terminated altogether if the No Action Alternative was selected by the Forest Service. Because of this, describing the baseline conditions as those that would exist after the legacy mining features were cleaned up would be speculative.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Samuel Penney (Chairman)	19396	41	Inadequate No Action Alternative As the Tribe stated in its scoping and DEIS comments, a true no action alternative is not that the site will remain polluted/degraded since Perpetua is under an obligation to remediate all of the pollution/impacts under its broad, current liability. The Agency cannot skew the no action alternative to argue that approval of the Project is needed to clean up the site, when cleanup is already mandated by federal law. The SDEIS provides no such acknowledgement, and instead offers a vague, incomplete, and narrow description of the site. The SDEIS notes, "...the Plan would not be approved and no mining, ore processing, or related activities would occur..." Thus, in the no-action alternative, the Forest needs to fully review Perpetua's current liabilities and the extent of remediation that would be accomplished if Perpetua met its current liabilities, independent of approval of the Project under applicable federal laws such as the Clean Water Act and/or Comprehensive Environmental Response, Compensation and Liability Act ("CERCLA"). The Forest's review in the SDEIS should have included a full evaluation of the Tribe's recommended approach for a "no action alternative including cleanup" for the site, as described in the attached October 27,2020, memo prepared by Jim Kuipers, P.E., Kuipers & Associates.	ALT	The history of the CERCLA actions at the Stibnite Location are described in Section 1.3 of the SDEIS. That narrative describes Perpetua's liability to conduct response activities at the site under the January 15, 2021 ASAOC. Any consideration of potential future cleanup activities at the Stibnite site needs to consider the terms of the ASAOC between Perpetua, EPA and the Forest Service. Importantly, section 9 and 12 of the ASAOC recognize that Perpetua did not create the historic environmental issues at the site and does not admit to any liability under the ASAOC. Phase 1 of the ASAOC includes certain time critical removal actions that would be implemented by Perpetua between 2021 and 2025. The Phases 2 and 3 under the ASAOC would be optional if Perpetua received approval for the SGP and plans for these future activities under the ASAOC can be terminated by Perpetua and the Agencies if the proposed new mining at Stibnite is not approved (the No Action Alternative). As described in Section 1.3, because these phases are optional, they are not considered to be reasonably foreseeable for the purposes of the SGP EIS. The description of the No Action Alternative in Section 2.3 of the SDEIS correctly limits the reasonably foreseeable CERCLA response actions to those directed by the ASAOC.
Samuel Penney (Chairman)	19396	52	2.6 Alternatives Considered but Eliminated from Further Detailed Study Economic viability should not be used as a rationale for not minimizing environmental effects under NEPA.	ALT	CEQ has stated that " <i>Reasonable alternatives include those that are practical or feasible from the technical and economic standpoint and using commons sense, rather than simply desirable from the standpoint of the applicant.</i> " (40 Most Asked Questions Concerning CEQs NEPA Regulations, Q/A 2a, 51 FR 15618, April 25,1986). CEQ has also stated, " <i>an agency's responsibilities to examine alternatives sites has always been bounded by some notion of feasibility</i> " and, " <i>there is no need to disregard the applicant's purpose and needs and the common sense realities of a given situation in the development of alternatives</i> " (CEQ Guidance Regarding NEPA Regulations, 48 FR 34263, July 28, 1983). The 2021 MMP describes Perpetua's primary objectives based on professional examination of the mineral reserves, economics, and common sense (M3 2021). The 2021 MMP is based on economic and profitable production of the recoverable metal values, constrained by the site-specific physical conditions at the site such as geology, mineralization, topography, hydrology, and in this case, the legacy mining features. There is no need to disregard Perpetua's purpose and need for the Project and to develop alternatives that may be purely conjectural and whose implementation would be remote and speculative.
Samuel Penney (Chairman)	19396	367	Because the Forest does not deem impacts to soils, wildlife, and vegetation as significant issues in the SDEIS, none of the action alternatives were developed to minimize impacts to plant and wildlife habitat. Both action alternatives pose significant and adverse impacts to wildlife and wildlife habitat, especially to wolverine (>2,000 acres directly impacted), alpine species, wetland and riparian wildlife, and migratory birds.	ALT	Section 1.10.1 of the SDEIS reviews the Forest Service's opinion on the significant issues that drive the development of action alternatives. This does not eliminate the evaluation of other issues in the EIS for other environmental resources as described in Section 1.10.2 and Table 1.10-1 of the SDEIS. A number of issues were identified for soils, vegetation, and wildlife and impacts to these resources were evaluated in Sections 4.5, 4.10, and 4.13 of the EIS, respectively.

Geologic Resources and Geotechnical Hazards

Jim Constantopoulos	1007	2	Upon reviewing the EIS and other available materials, I find that project is well thought out, sustainable, economically viable, and environmentally sound. The viability of the project is reflected in the statement in the DEIS "Midas Gold's compilation of historic geologic and mineral resource data in addition to data acquired from their own exploration drilling programs (Appendix 1) have clearly identified a remaining mineable resource..." This is further reflected in the statement, "Midas has proposed a reasonable plan of operations for development based on their knowledge of the mineral resources in the project area and the infrastructure necessary to support mineral development of this scale." While the gold and silver grades and indicated resources are impressive, I'm more impressed that this will be the only U.S. mine project to provide much-needed antimony for domestic markets. In several of my courses, we discuss the	GEO	No further response required. General in nature or position statement.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			green energy transition and critical minerals as defined in Executive Order 13817. Students need to understand where we are as a nation regarding mineral dependency, and this project is an excellent example of what we can do to reduce that dependency.		
Dan Garner (Representative, District 34)	7142	2	Currently, China, Russia and Tajikistan control 90% of the global antimony supply and the US has no domestically mined source. The Stibnite site is the only identified reserve of antimony in the US and would be a key factor in reducing our reliance on foreign imports. Supplying antimony, which is used in production of ammunition, can help secure our national defense and protect our service members.	GEO	No further response required. General in nature or position statement.
Greg Lanting (Representative)	7147	3	Furthermore, this project will provide the much-needed critical mineral, antimony. The project site has an estimated 148 million pounds of antimony reserve. With the current political environment, domestically mining this important resource is crucial now more than ever. Further, Perpetua can enter into mill-toll or similar agreements that keep Perpetua in control of the product.	GEO	No further response required. General in nature or position statement.
Britt Raybould (Representative)	7180	2	If approved, Stibnite Gold would be the only domestically sourced antimony site in the US. Currently, our nation depends on Chinese and Russian imports of this critical mineral, which is used to manufacture ammunition and semiconductors. Supplying antimony from Idaho can help secure our national defense and protect our military heroes.	GEO	No further response required. General in nature or position statement.
Doug Pickett (Representative, District 27)	7187	2	Idaho has an incredible environment with an abundance of critical natural resources. Currently, 90-percent of the global antimony supply is found in China, Russia, and Tajikistan. With antimony being used to manufacture ammunition and semiconductors, I feel it would be smarter to domestically source this material, rather than relying on foreign imports; thus, potentially putting our country at risk.	GEO	No further response required. General in nature or position statement.
Dustin Manwaring (Representative)	7189	3	As a US citizen, we cannot ignore how the production of antimony at Stibnite will strengthen our national security. Right now, the U.S. relies primarily on China and Russia for this mineral- because there is no domestically mined source of antimony. With the recent pandemic and the incursion in Ukraine, Americans value a domestic supply chain for strategic minerals more than ever. The Stibnite Gold Project could produce over 100 million pounds of antimony and meet roughly 35% of U.S. demand in the first couple years of production. Antimony is used in every bullet that our armed services fires, in lead-acid batteries and in flame retardants.	GEO	No further response required. General in nature or position statement.
Matt Bundy (Representative)	7197	3	As a 20-year veteran of the Air Force, I am aware of the significance of having a domestic supply of antimony for our defense and the safety of our service members. The Stibnite Gold Project would enable the first antimony source to be mined domestically. Our country is vulnerable because of our reliance on antimony from foreign countries. Not supporting this project would be a serious mistake. Particularly in light of prior indications of interest in the project from the Department of Defense. In September, the company was awarded a \$200,000 SBIR grant from the DoD to examine whether the antimony at Stibnite can meet military demands.	GEO	No further response required. General in nature or position statement.
Ted Hill (Representative, District 14, Seat A)	7204	2	Antimony is a critical mineral needed for primers in hundreds of munition types required by the U.S. Military. Currently the United States is relying on China, Russia and Tajikistan who control 90% of the global supply as we do not have a domestically mined source. This makes the United States extremely vulnerable. The Stibnite project has a large antimony resource, 148 million pounds. When mined, this resource could satisfy about 35% of overall commercial demand in the U.S. and for antimony and all Department of Defense demand. This is crucial and timely.	GEO	No further response required. General in nature or position statement.
Kenny Wroten (Representative, District 13, Seat B)	7214	3	Moreover, Perpetua has also designed the Stibnite Project with the environment in mind. The company has outlined, in immense detail, the repair of past mining legacies, while extracting critical elements such as antimony. By mining this critical resource, which is currently the only identified source of antimony in the US, it would enhance our domestic production; all while removing hundreds of pounds of metal and contaminants in our waterways, and will enhance more than a dozen miles of streams.	GEO	No further response required. General in nature or position statement.
Stephanie Jo Mickelsen (Representative,	7258	2	In addition to my new role as a Representative for District 32, I also serve as the State Director of the Idaho Farm Bureau. What I hear from farmers across our state are concerns of economic instability, especially given Russia's invasion of Ukraine. It's raising prices on many products, but also raising questions about our national security. Permitting Stibnite Gold would allow Perpetua the ability to	GEO	No further response required. General in nature or position statement.

District 32, Seat A)			locally source antimony, which is a key component of ammunition used by the US military. Currently, Russia, China, and Tajikistan account for 90-percent of the global antimony supply, so approval of Stibnite would bolster our national security.		
Conway Ivey (Executive Chairman, Ivy Minerals, Inc.)	13274	4	I was surprised to see that the SDEIS makes almost no mention of the value of the MMP in providing a domestic source of a strategic mineral, antimony. Executive Order 14017 (EO), signed by President Biden, directed the federal government to undertake a review of vulnerabilities in critical mineral and material supply chains in the US, with a goal of identifying bottlenecks in those minerals and approaches to increase their domestic production. This EO reflects a new political and social realization that the United States is vulnerable when critical minerals used in its manufacturing and defense industries are primarily or entirely sourced from geopolitical entities that are unreliable, or openly hostile to our country. Antimony trisulfide is essential to national defense as a key component for a wide range of munitions in the US defense arsenal. The SGP would be the only domestically mined source of antimony and has one of the largest resources in the world not controlled by China or Russia. The SDEIS says that the MMP would produce 148.7 million tons of antimony, meaning that this one mining project would likely satisfy the strategic need to source this mineral from the United States itself. The importance of this resource is underscored by the December 19, 2022 Department of Defense ("DoD") Press Release announcing a \$24.8 million award to Perpetua which states the SGP "is the sole domestic geologic reserve of antimony that can meet DoD requirements". Its press release goes on to say, "This investment is essential to ensure the timely (emphasis mine) development of a domestic source of antimony trisu/fide for the manufacturer of small arms and medium caliber cartridges, as well as many other missile and munition items." Downplaying or ignoring this value of the MMP is a major shortcoming of the SDEIS, which needs to be remedied with a greater discussion and analysis in the Final EIS because it is another major reason the USFS should approve the MMP. If these economic and strategic mineral benefits, were all that was provided by the MMP, they would support and justify USFS approval of the project. But they are far from the only benefits.	GEO	<p>Additional narrative has been added to the Final EIS to discuss the EO 14017 relevance to the SGP. Narrative has also been added to Section 3.2.3 of the Final EIS to discuss the Department of Defense (DoD) actions related to the Project.</p> <p>Add the following narrative to the end of Section 3.2.3:</p> <p><u>Federal Administrative Actions Related to Antimony Supply</u></p> <p>A number of federal administrative actions have been taken that relate to the marketplace for antimony supply.</p> <p>On December 17, 2017, the U.S. Geological Survey published the report <i>Critical Mineral Resources of the United States - Economic and Environmental Geology and Prospects for Future Supply</i>. Chapter C of that work was on Antimony (USGS Professional Paper 1802-C.) That report described the uses, demand, and supply for various forms of antimony and showed that China produced about 80 percent of the world's supply of antimony. The United States was described as essentially importing all its supply of antimony, with over 67% coming from China.</p> <p>On September 30, 2020, President Trump signed the <i>Executive Order Addressing the Threat to the Domestic Supply Chain From Reliance on Critical Minerals from Foreign Adversaries and Supporting the Domestic Mining and Processing Industries</i> (EO 13953). The EO declared a national emergency to deal with the threat of our reliance on critical minerals from foreign sources. It required various federal agencies to provide reports describing the threat and recommending any actions necessary to address the threat. It established a policy that relevant federal agencies should prioritize expansion and protection of the domestic supply chain for critical minerals.</p> <p>President Biden signed the <i>Executive Order on America's Supply Chains</i> (EO 14017) on February 24, 2021. It ordered reviews of six sectors (defense, commerce and homeland security, energy, agriculture, transportation, and health and human services) and a review of four classes of products where American manufacturers rely on imports. Among other topics, it required the Department of Defense to submit a report identifying risks in the supply chain for critical minerals and other strategic materials and recommendations to address those risks.</p> <p>On June 8, 2021 the DoD released the <i>Strategic and Critical Materials 100-day Sector Review Report</i> as directed by EO 14017. The DoD defined strategic and critical minerals as those that support military and essential civilian industry and are not found or produced in the U.S. in quantities to meet the needs of the nation. It listed a number of materials it identified as "unclassified base case shortfall materials" that, during a national emergency, the U.S. would be likely to face inadequate supply of these materials due to an inability to obtain adequate supplies from foreign sources. Antimony was included in the list of unclassified base case shortfall materials. The report included a number of recommendations related to expanding sustainable domestic production of strategic and critical materials, including recycling and recovery from mine wastes.</p> <p>On February 22, 2022 the U.S. Geological Survey released a new list of 50 mineral commodities critical to the U.S. economy and national security. Antimony was included in the list. The short-term importance of the new list is that it is intended to focus the USGS in its ongoing research quantifying potential sources of critical minerals within the U.S., including ores and mining wastes.</p> <p>In February 2022 the DoD released its report on <i>Securing Defense-Critical Supply Chains</i>, in response to EO 14017. Among other topics, the report recommended that the DoD enhance</p>

					<p>and grow the U.S. industrial base by supporting development of domestic production capacity for supply chains that are critical for national defense. In the included update for the <i>Strategic and Critical Materials 100-day Sector Review</i>, the DoD stated it intends to facilitate business-to-business ties domestically and with allies, to mitigate vulnerabilities for strategic and critical materials.</p> <p>On December 19, 2022 the DoD issued a \$24.8M Critical Minerals Award through its Defense Production Act (DPA) Investments Program and the Air Force Executive Agent, using funds from the Ukraine Supplemental Appropriations to Perpetua Resources to secure an American source of critical minerals for missiles and munitions. The funds are intended to be used to complete environmental and engineering studies necessary to obtain a Final EIS and ROD and other ancillary permits through 2024. The DoD said, "This investment is essential to ensure the timely development of a domestic source of antimony trisulfide for the manufacture of small arms and medium caliber cartridges and well as many other missile and munitions items." The DoD announcement of the award also said, "This award does not interrupt the ongoing National Environmental Policy Act (NEPA) review process, nor does a DPA Investment confer any right or benefit through the permitting process."</p>
Kevin Vivian (President, Agri-Service)	14669	2	In addition to the gold that will be mined at the future site, the Stibnite Gold Project will enable America to resume domestic production of antimony, which the U.S. government considers a "critical mineral" due to its use in national defense, aerospace, and energy. According to the U.S. Geologic Survey (USGS), our country is currently not producing any antimony domestically, leaving China, Russia, and Tajikistan as the leading sources of the mineral for the U.S. Antimony continues to become ever more critical to our country's national and economic security. From its uses in ammunition and primers, to solar panels and renewable energy batteries, it is imperative that we secure a US supply of this critical mineral. The Stibnite Gold Project will enable America to resume mining of this important mineral on our own soil. And it will also allow us to build up a stockpile of antimony as recommended by the Department of Defense to prepare for a projected shortfall of the mineral.	GEO	No further response required. General in nature or position statement.
Bowen, Mike (Executive Director, New Mexico Mining Association)	16872	2	As we explained in our October 2020 letter on the DEIS, New Mexico has many mining districts that were developed in the same timeframe as the Stibnite Mining District where mining started in the late 19th century and continued through the first half of the 20th century. The MMP redevelopment, remining, and restoration proposal analyzed in the SDEIS is thus of interest to NMMA - especially in light of recent policy developments pertaining to critical minerals and evaluating old mine wastes as a potential source of critical minerals. Both the Biden Administration and Congress have recently developed policies that favor producing critical minerals from old mine wastes. For example, the 100-day report entitled "Building Resilient Supply Chains, Revitalizing American Manufacturing, and Fostering Broad Based Growth", explicitly requires the Secretaries of Agriculture and the Interior to evaluate reprocessing mine wastes as a viable source of critical minerals. As a remining and reprocessing project that will recover the critical mineral antimony from legacy mine wastes, the SGP could become the first project to confirm the viability of producing a critical mineral from legacy mine wastes. With the enactment of the November 2021 Infrastructure Investment and Jobs Act (IIJA), which is also known as the Bipartisan Infrastructure Law, Congress established several critical minerals mandates. Section 40206 of the IIJA notes that permitting delays are a principal factor in contributing to the nation's dangerous reliance on foreign countries for critical minerals, and directs the Secretaries of Agriculture and the Interior to prepare a report within one year to make recommendations to streamline the permitting process. The IIJA also created a \$510.7 million scientific research program for the U. S. Geological Survey (USGS) and directed that most of this funding be used for critical minerals research. As part of the IIJA-funded critical minerals research program, the USGS is studying the potential for critical minerals in mine waste. In light of these critical minerals and remining directives, the SGP becomes a project of national importance. The Forest Service needs to consider this importance as it finalizes the National Environmental Policy Act (NEPA) process for the SGP, prepares the Final Environmental Impact Statement (FEIS), and issues the Record of Decision (ROD) to approve the SGP.	GEO	No further response required. General in nature or position statement.

			The national importance of the SGP demonstrating the feasibility of producing a critical mineral from legacy mine wastes dictates that the Forest service should expedite issuing the ROD.		
Bowen, Mike (Executive Director, New Mexico Mining Association)	16872	3	The Department of Defense's December 19, 2022 announcement that it has awarded Perpetua a \$24.8 million Title III Defense Production Act (DPA) grant to advance the SGP signals the U.S. military urgently needs the antimony from the SGP. The statement that the Stibnite deposit is "the sole domestic geologic reserve of antimony that can meet Department of Defense (DoD) requirements "is sobering and means that the Forest Service needs to approve this project quickly - preferably as early as possible in 2023 - for national security and defense reasons. The following excerpts from DoD's announcement also underscore the national importance of the SGP: "This investment is essential to ensure the timely development of a domestic source of antimony trisulfide for the manufacture of small arms and medium caliber cartridges, as well as many other missile and munition items." "This action reinforces the Administration's goals to increase the resilience of our critical mineral supply chains while deterring adversarial aggression." The obvious conclusion to be reached from DoD's announcement is that without the antimony from the SGP, the country's vulnerable antimony supply chain compromises the U.S. military's ability to manufacture the weapons needed to protect the country. The U.S. currently imports 84 percent of the antimony we need, with about half of the imported antimony coming from China. This high level of import reliance - especially from China – may be one of the main reasons the military is eager to have a reliable domestic source of antimony from the SGP. The need for the antimony from the SGP is increased by DoD's admission that the SGP as the only antimony reserve that meets the military's technical specifications. Given these facts, it seems obvious that the SGP needs to be built and operated as soon as possible to strengthen our antimony supply chain and reduce our reliance on China and other foreign countries for this critical mineral. The only way for this to happen is for the Forest Service to expedite publication of its FEIS for the SGP and issue the ROD approving the SGP.	GEO	The Payette and Boise National Forests have made the timely completion of the SGP Final EIS a high priority.
Lehrer, Laura	16878	4	The lack of monitoring of the tailings site. Failure of the dam would be swift and catastrophic. Technology is available to apply more rigorous standards to the construction and maintenance of this part of the project which would reduce the risk, but it is not being required by the Forest Service. We can, and should apply higher standards.	GEO	The IDWR is the proper authority in Idaho to regulate design, construction, and operation of dams, including tailings disposal facilities. These requirements are cited in Section 3.2.3 of the SDEIS. Perpetua would need to comply with the IDWR regulations and requirements for its TSF. The monitoring requirements for the TSF would be established by the IDWR permitting process and the Forest Service recognizes the primacy of the IDWR in these matters, so has not specified monitoring of the TSF in the EIS.
Hendrickson, Emily (President, Women's Mining Coalition)	17429	1	The U.S. is fortunate that Perpetua Resources Ltd. (Perpetua) is proposing to develop the Stibnite Gold Project (SGP) in Valley County, Idaho to produce gold and the critical mineral, antimony, because this project will achieve two important missions: 1. It will clean up an area where World War II- and Korean War-vintage mine wastes are degrading water quality and preventing fish migration; and 2. It will supply the country with an urgently-needed domestic source of antimony. The U.S. Department of Defense's (DoD's) December 19, 2022 announcement to award Perpetua up to \$24.8 million in a Title III Defense Production Act grant describes the SGP as having "the sole domestic geologic reserve of antimony that can meet Department of Defense (DoD) requirements." DoD knows the antimony at the SGP is suitable for military applications because the federal government "produced antimony trisulfide for the U.S. ammunition industrial base during World War II and the Korean War" from the Stibnite Mine. This emergency wartime mining effort created the mine wastes that are currently leaching arsenic, antimony, and other contaminants into the Stibnite mine area watershed and obstructing fish migration corridors.	GEO	No further response required. General in nature or position statement.
Hendrickson, Emily (President, Women's Mining Coalition)	17429	3	Based on the DoD's December 19, 2022 announcement, it is clear the U.S. military urgently needs the antimony contained in the Stibnite gold-antimony deposit. The DoD awarded a \$24.8 million Title III Defense Production (DPA) grant to Perpetua to help the Company "complete environmental and engineering studies necessary to obtain a Final Environmental Impact Statement, a Final Record of Decision, and other ancillary permits." The following statements from DoD's December 19, 2022 press release underscore the importance of the SGP to the Nation: "This investment is essential to ensure the timely development of a domestic source of antimony trisulfide for the manufacture of small arms and medium caliber cartridges, as well as many other missile and munition items." "This action reinforces	GEO	No further response required. General in nature or position statement.

			the Administration's goals to increase the resilience of our critical mineral supply chains while deterring adversarial aggression." As the Nation's "sole domestic geologic reserve of antimony that can meet Department of Defense (DoD) requirements," there can be no doubt that obtaining antimony from the SGP is essential for our national defense and security. Our October 2020 comments on the DEIS described WMC's longstanding concerns about the Nation's reliance on foreign countries for many critical minerals, including antimony. We noted that the U.S. Geological Survey's 2020 Minerals Commodity Summaries showed that the U.S. imported 84 percent of the antimony the country used in 2019. Over one-half of this antimony was imported from China. Today, the country's import reliance on China for antimony remains the same. We continue to import 84 percent of the antimony we need, with much of it coming from China. DoD's Title III DPA award in support of the SGP suggests that DoD considers this substantial import reliance to be an untenable situation for the U.S military and a significant threat to national security. In addition to its critical military applications, antimony from the SGP will be used in utility-scale storage batteries. In August 2021, Perpetua announced that it had entered into an agreement to supply a portion of antimony production from the SGP to Ambri Inc. ("Ambri"). Ambri is a U.S. company that has developed an antimony-based, low-cost liquid metal battery for the stationary, long-duration, daily cycling energy storage market. The antimony-based Ambri battery combines technological innovation with commercial applications for low-cost, long lifespan and safe energy storage systems that will increase the overall contribution from renewable sources to help enable the transition to green, carbon-free power grids. The clean energy use of antimony is another compelling reason why the SGP is so important to the Nation.		
Idaho Regulatory Agencies	17718	68	Instead of mixing various IDAPA sections IDL suggests separating the sections by State agencies.	GEO	Edits made. Made the following changes to these two subsections of Section 3.2.3. "Idaho Department of Water Resources Rules - Idaho dam safety statutes are enumerated in Section 42-1709 through Section 42-1721 of the Idaho Code. Mine tailings impoundment structures greater than or equal to 30 feet high are regulated by the IDWR in the same manner as water storage projects, with an additional provision that a surety bond be secured by the owner, payable to IDWR to ensure the TSF is placed in a safe and maintenance-free condition upon decommissioning. Design and construction requirements for Mine Tailings Impoundment Structures are described in the IDAPA Section 37.03.05, while Section 37.03.06 describes rules for the safety of dams. Idaho Department of Environmental Quality Cyanide Processing Rules - These rules establish a permitting process to construct, operate and close facilities intended to contain, treat or dispose of water containing cyanide. The IDAPA 58 Administrative Rules (58.01.13) address ore processing by cyanidation and apply to processing facilities, tailings dams, pipelines, and process ponds if they contain cyanide process water. Idaho Code § 42-1711; Idaho Administrative Procedure Act ("IDAPA") 37.03.05.40."
Idaho Regulatory Agencies	17718	69	"There are no known or suspected cave or karst resources in the analysis area. " may be true. However, your inference is incorrect: "The extensive metamorphism of the carbonate rocks in the area, as well as level of exposure relative to the original ground surface where caves and karst would form, would generally preclude the existence or preservation of such features in the area." Karst forms in all three carbonate rocks: limestone, dolostone, and marble. It is well known that significant economic ore deposits accumulate in the voids in karst rocks, including marble, especially where mineral-bearing thermal or sulfide-rich solutions have modified the bedrock.	GEO	Edits made. Changed Section 3.2.4.5 as follows: "There are no known or suspected cave or karst resources in the analysis area. The extensive metamorphism of the carbonate rocks in the area, as well as level of exposure relative to the original ground surface where caves and karst would form, would generally preclude the existence or preservation of such features in the area."
Idaho Regulatory Agencies	17718	78	For clarity, please include "view" when stating plan, as in plan view (or map view). To write for the reader's perspective, please use commas to separate clauses. Example for sentence 2: It would be roughly circular in plan <u>view</u> , with a lobe extending into the Homestake area <u>towards</u> the northeast, and another lobe <u>extending in</u> towards the south end of the pit.	GEO	Edits made. In Section 4.2.2.2 and the paragraphs for Yellow Pine pit, Hangar Flats pit, and West End pit changed "plan" to "Plan view".

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Idaho Regulatory Agencies	17718	79	"The underlying bedrock is more than sufficiently competent to support the proposed structures because the rock types consist of quartz monzonite, diorite, granite and rhyolite (Tierra Group 2018)." Rock type by itself in no way proves that there is sufficient competence to support structures. Doesn't Tierra Group, 2018 discuss some type of fracture analysis, etc. as determined from detailed study of adjacent outcrop, or by detailed borehole rock core analysis? Please provide data to support this statement.	GEO	The foundation characteristic within the SGP is described in Section 3.2.4.7 of the EIS. The bedrock strength characteristics, including fracturing, of the SGP area are described in a number of the technical reports cited in this section and the bedrock is generally described as being very competent. Stability analyses of the TSF, including strength characteristics of the bedrock and unconsolidated materials under the TSF are reviewed by the Tierra Group.
Benjamin Davenport, Executive Director, Idaho Mining Association	18777	12	<p>VII. Comprehensive Cleanup of the Stibnite Mine Cannot Happen Without the MMP</p> <p>The MMP is essential to the eventual comprehensive cleanup of the Stibnite Mine area because revenue from the production of gold and antimony from the Stibnite Mine will become the economic driver that can help fund future restoration of legacy features that are outside the project boundary for the MMP. Although the MMP will remediate numerous mine features in the MMP project boundary, there are some problematic legacy mine features outside of this boundary that will continue to leach metals into area streams after mining is completed. The January 2021 Administrative Settlement and Order on Consent (ASAOC) between Perpetua, the Forest Service and the U.S. Environmental Protection Agency (EPA) described in Section 1.3 of the SDEIS is designed to remediate the legacy features outside of the MMP project boundary. Perpetua initiated Phase 1 of the ASAOC in July 2022. In the future, Perpetua may be able to pursue the conceptual site restoration measures in Phases 2 and 3 of the ASAOC if and when Perpetua is producing gold and antimony from the Stibnite Mine.</p> <p>Under Phase I of the ASAOC, Perpetua is voluntarily addressing several areas identified as being time-critical by implementing restoration measures that will eliminate or reduce contaminant sources from these areas as quickly as possible. The Forest Service and the EPA are directing and supervising the ASAOC Phase I remediation activities, which will cost Perpetua \$12 million to complete. In addition to these direct, on-the-ground remediation costs, Perpetua provided the agencies with a \$7.5 million performance bond to guarantee this work.</p> <p>The ASAOC Phase I water quality improvements are anticipated to be completed by 2025 and include constructing stream diversion ditches to divert water away from legacy mine wastes that are contaminating area streams, removing approximately 325,000 tons of legacy development rock and tailings from locations in Meadow Creek and the EFSFSR that are currently adversely impacting water quality. Phase I also entails conducting baseline studies at five historic mine adits that are discharging mine drainage.</p> <p>Once the SGP has all of its operating permits and production is underway, Phases 2 and 3 of the ASAOC give Perpetua the option to remediate additional legacy mine features located outside the MMP project boundary. These phases will require additional baseline data and engineering studies and probably entail additional permitting.</p> <p>The sequential combination of the ASAOC Phase 1, the MMP, and the ASAOC Phases 2 and 3 would ultimately achieve a comprehensive, site-wide restoration and cleanup of the Stibnite Mine site. It is therefore imperative that the Forest Service, the U.S. Army Corps of Engineers, and the Idaho State regulatory agencies take immediate steps to set this remediation sequence in motion.</p> <p>The opportunity to achieve a complete cleanup of the Stibnite Mine site that Perpetua will subsidize is both unique and important. There may not be a similar opportunity in the future if the SGP is not built and operated. If this occurs, the lost opportunity costs would be enormous and the <i>status quo</i> environmental problems would adversely affect water quality, fish habitat, and ultimately people and communities for many years.</p>	GEO	The ASAOC work is separate from the NEPA permitting process and was initiated in direct response to a Citizens Clean Water Act Lawsuit by the Nez Perce Tribe.
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	7	Establishing an Independent Tailings Review Board (ITRB) for the tailings storage facility including the buttress dam and conducting regular independent reviews as a mitigation measure to ensure geotechnical stability and protection of surface resources.	GEO	The IDWR is the proper authority in Idaho to regulate design and operation of dams, including tailings disposal facilities. Perpetua would need to comply with the IDWR regulations and requirements for its TSF. The Forest Service supports the inclusion of an ITRB as part of the site-specific, IDWR requirements for monitoring and operating the SGP TSF and would request that this be part of the IDWR permit conditions.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	41	<p>Mitigation Measures for Geotechnical Stability</p> <p>The SDEIS analysis does not recommend any additional geotechnical stability mitigation measures beyond those identified in Section 2.4.9. Although the TSF dam is designed to meet and exceed regulatory stability criteria, recent studies of dam failures have established that the dominant cause of failures arises from deficiencies in engineering practice associated with the spectrum of activities embraced by design, construction, quality control, and quality assurance. Therefore, there is credible information highlighting that, even assuming that the dam and buttress are adequately designed, dam incidents could still happen due to human-caused errors during construction and operations. A best practice to mitigate this, is the establishment of an Independent Tailings Review Board (ITRB) and regular independent reviews during design, construction, operations, and closure. An ITRB and regular independent review is a best practice for new tailings dam facilities (with high or greater consequence classifications) in the Global Industry Standard on Tailings Management.</p> <p>The State of Idaho's dam safety regulations do not appear to require independent review. Therefore, we recommend that the FEIS include a requirement that an ITRB be established and regularly conduct independent reviews as a mitigation measure to ensure geotechnical stability, including during seismic events, and protection of surface resources. We note that the Forest Service is requiring establishment of an ITRB in RODs for the Pinto Valley Mine (AZ) and Kensington Mine (AK), based on the global standard and FEMA Federal Guidelines for Dam Safety Risk Management.</p>	GEO	The IDWR is the proper authority in Idaho to regulate design and operation of dams, including tailings disposal facilities. Perpetua would need to comply with the IDWR regulations and requirements for its TSF. The Forest Service supports the inclusion of an ITRB as part of the site-specific, IDWR requirements for monitoring and operating the SGP TSF and would request that this be part of the IDWR permit conditions.
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	42	<p>Geotechnical Stability of Mine Access Roads</p> <p>When comparing geotechnical stability related to mass wasting events (i.e., landslides, rockfalls, and avalanche paths) of the 2021 MMP Alternative's Burntlog Route and the Johnson Creek Route Alternative, EPA recommends the FEIS consider the implementation of proposed environmental design features (EDFs) for the two Action Alternatives in the alternatives analysis. For example, for existing areas of landslides and rockfalls, geotechnical design considerations and improvements to existing roads with EDFs could address the issues raised as concerns for the Johnson Creek Route Alternative with geotechnical stability potentially improving as a result of the alternative. EPA also recommends that the FEIS clearly state in Section 4.2.2.3 Johnson Creek Route Alternative that the EDFs proposed for the 2021 MMP Alternative's Burntlog Route also apply to the Johnson Creek Route Alternative.</p>	GEO	<p>The effectiveness of the proposed EDFs for addressing mass wasting hazards along both access road alternatives would depend on the detailed design and installation quality of the EDF actions, and the natural conditions at each site. It would be speculative at this time to make assumptions that site-specific application of the EDFs would eliminate certain mass wasting hazards and thus remove certain landslide or rockfall sites from the comparison of the access road alternatives. Therefore, the Forest Service believes a valid comparison of the two access road alternatives has already been included in the SDEIS. The narrative of Section 4.2.2.3 has been edited to include a statement that the EDFs described in Section 4.2.2.2 for landslides, rockfalls, and avalanches would also apply to the Johnson Creek Route Alternative.</p> <p>At the end of the first paragraph in Section 4.2.2.3 the following sentence was added: "The EDFs for landslides, rockfalls, and avalanches described in Section 4.2.2.2 for the Burntlog Route would also apply to the Johnson Creek Route Alternative."</p>
Small, Nathan (Chairman, Fort Hall Business Council, Shoshone-Bannock Tribes)	18903	18	While sustaining domestic production of critical minerals is a broad national goal, implementing large scale production measures should not absolve mineral development companies of obligations to extract those minerals in a responsible manner. The Tribes have noticed a growing trend to emphasize the demand for domestic production of rare minerals as a justification for the mineral extraction, and the expediency of environmental review; with a tendency to 'lower the bar' for remediation and on-site monitoring during mining activities. Creating meaningful mineral development operations requires significant investments in environmental remediation and resource protection for decades to come. In the present case, if/when the 'critical' minerals become obsolete commodities, the mining company should still be prepared to fully implement the required remediation and not be allowed to forgo actions that are committed to in the mine plan of operations by increasing the reclamation bond up front; in other words, pay the up-front cost of reclamation at the outset of mining rather than depend on uncertain mineral markets years from now. While a great deal of effort is going into justifying a permit from the mining operation, a clear rationale of 'why' creating irreversible damage to the South Fork is actually in the public interest has not been presented by this SEIS.	GEO	In compliance with state and federal requirements of approval that regulate the reclamation of all parts of the 2021 MMP, Perpetua would be required to post adequate surety to reclaim the disturbances caused by the operations. These regulations allow the mining operators to submit applications for adjustments to the operations due to economic or physical conditions that may become apparent after the initial permit approvals. In any case, the regulations do require full reclamation of all disturbances created by the operations.
Small, Nathan (Chairman, Fort Hall Business Council,	18903	30	Antimony reserves at SGP are highly insignificant compared to major global suppliers. Additionally, because Perpetua does not have an antimony refinery and will have to sell ore to a foreign refinery (there are no refineries in the US) yet to be determined, which means storage of the antimony ore will be required, it is clear that justifying this project under the critical minerals program poorly advised.	GEO	The 2021 MMP describes that antimony concentrate would be produced from the antimony ore as it is encountered. This concentrate would be shipped offsite to be sold to a smelting customer.

Shoshone-Bannock Tribes)					
Small, Nathan (Chairman, Fort Hall Business Council, Shoshone-Bannock Tribes)	18903	31	Because of the small reserves of antimony at SGP and because mining is an unsustainable activity as the resources are finite, please establish an antimony recycling program for Idaho and use your financial resources to educate the public regarding the finite resources that mining highlights.	GEO	No further response required; unrelated to the decision being made.
Small, Nathan (Chairman, Fort Hall Business Council, Shoshone-Bannock Tribes)	18903	38	The Shoshone-Bannock Tribes request the USFS require focused analysis of earthquake impacts to on-site and off-site resources including: static analysis, response spectra analysis and time history analysis with a detailed report provided on stability features of the Tailings Structure under stress conditions, impacts to resources should a catastrophic failure occur and location dispositions of materials should this occur.	GEO	Seismicity of the region around the SGP is discussed in Section 3.2.4.6 of the SDEIS. This information includes detailed seismic hazard analysis prepared by Golder Associates (2021). The relative stability of the TSF embankment with and without the presence of the adjacent development rock buttress is discussed in SDEIS Section 4.2.2.2 and Table 4.2-1. The stability evaluations of the TSF under stress conditions calculated for the seismic design criteria are discussed in Section 4.2.2.2 of the SDEIS and show the TSF embankment would have factors of safety well above the required values and therefore is expected to be safe from earthquake induced damage that would result in a catastrophic release of tailings. The Forest Service has therefore not conducted an impact evaluation of such a release because such would be a worst-case analysis that is specifically not required by NEPA.
Deantha Skibinski, Executive Director, Alaska Miners Association	18899	9	<p>Antimony from the SGP is Uniquely Suited to Meet the U.S. Military's Needs</p> <p>In its December 19, 2022 announcement of the \$24.8 million Title III Defense Production Act (DPA) award to Perpetua to help complete the NEPA process⁴, the Department of Defense said the SGP contains “the sole domestic geologic reserve of antimony that can meet Department of Defense (DoD) requirements⁵.” The DoD announcement includes other statements that underscore the national security importance of this project:</p> <p>“This investment is essential to ensure the timely development of a domestic source of antimony trisulfide for the manufacture of small arms and medium caliber cartridges, as well as many other missile and munition items.”</p> <p>“This action reinforces the Administration’s goals to increase the resilience of our critical mineral supply chains while deterring adversarial aggression.”</p> <p>The DoD award reflects the vulnerable status of the country’s antimony supply chain and our risky reliance on China and other foreign countries for much of the antimony the military needs to manufacture the “small arms and medium caliber cartridges,...missile and munitions items” that are clearly needed for national defense. According to the U.S. Geological Survey’s 2022 Minerals Commodity Summaries, the U.S. imports 84 percent of the antimony we use. Over half of this antimony was imported from China⁶. DoD’s Title III DPA award to support the SGP suggests that the U.S. military is concerned that the country’s substantial antimony import reliance creates an untenable situation for the U.S military and a significant threat to national security.</p>	GEO	<p>No further response required. General in nature or position statement.</p> <p>The Forest Service’s consideration of the Project on the basis of its ability to produce gold, silver, and antimony is described in SDEIS Section 1.6 as the Project’s Purpose and Need.</p>
Joseph Pietri	19062	10	Gold is the big item here but Antimony is conveniently located within the process of extracting gold and silver and Perpetua and the big investors were indeed fortunate to play out the green energy and strategic materials for defense card. No doubt using DC insiders for a \$25M boost. There are plenty of munitions in the US Arsenal Stores to Annihilate all of life on earth already and there has been for years. Just guessing on that but it is a bad trade off to the Earth to deliberately decimate thousands of acres to make rich people richer essentially. Let's face it, that is what this Mine is about pure Midas Greed. The restoration is a great marketing ploy but perhaps you can tell me how many of the same types of mines were restored and how many Companies pulled out, bankrupted and left a mess and a cleanup bill as big as the mess for the public to deal with. I'd like answers about that.	GEO	No further response required. General in nature or position statement.
Chris Hart	19206	2	Looking at landslide and avalanche data, it becomes obvious why the USFS named the Burntlog Route as its preferred alternative. According to the SDEIS, the Johnson Creek Route has 45 landslide and 94	GEO	No further response required. General in nature or position statement.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			avalanche paths. While these natural hazards aren't eliminated on Burntlog, they are reduced. Mine traffic will only have to pass 26 landslide and 38 avalanche paths while traveling on the Burntlog Route. Simply put, the Burntlog Route is safer. In fact, the SDEIS concludes utilizing Johnson Creek would increase the potential for accidents and spills associated with the project because of naturally occurring geohazards.		
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	625	"Both action alternatives would increase risks from mass wasting hazards ..." - Please provide rationale for the purpose of this paragraph or remove. It does not identify any cumulative impacts on geology or geotechnical hazards.	GEO	One of the issues considered in the SDEIS for geology is the geotechnical stability of SGP facilities. The risks posed by mass wasting hazards along both access road alternatives are described in Section 4.2.2. As described in SDEIS Section 5.2.2, the use of common access routes by the Project and RFFAs does not increase the likelihood of mass wasting but would increase the consequences of mass wasting impacts.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	117	As an update for the FEIS, this section may also discuss the grant awarded by the DOD to study production of antimony tri-sulfide for munitions, as announced in December 2022.	GEO	Edit has been made to the Final EIS. The following is included as a new third paragraph on page 4-8 of Section 4.2.2.2: "In December 2022 the Department of Defense announced that the Defense Production Act Investment Program would provide up to \$24.8 million for Perpetua to complete environmental and engineering studies necessary to obtain the permits for the SGP. The reason for this investment was to support the timely development of a domestic source of antimony trisulfide essential to national defense."
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	118	"High-antimony ore makes up about 30 percent of the ore in the Yellow Pine deposit and 54 percent of the ore in the Hangar Flats deposit..." Please correct: High antimony is approximately 21% of the YP mineral reserve and 36% of the HF reserve, as shown in table 1-4 of the Feasibility Study, (M3 2021). The stated numbers are not consistent with the resource either.	GEO	Edit has been made. In Section 4.2.2.2, the following edits were made: "High-antimony ore makes up about 30 21 percent of the ore in the Yellow Pine deposit and 54 36 percent of the ore in the Hangar Flats; there is no antimony ore in the Bradley tailings or West End deposit (M3 2021)."
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	119	"The SGLF has a post-mining land use designation of light industry, where it would remain un-reclaimed after mine operations and transferred to a third-party for light industrial uses ". Please clarify: According to the Valley Co conditions of approval, this facility would need to be reclaimed if a third party doesn't obtain a new Condition Use Permit for the facility within 3 years.	GEO	Edit has been made. On page 4-11 of Section 4.2.2.2: "The SGLF has <u>could have</u> a post-mining land use designation of light industry, where it would remain un-reclaimed after mine operations and <u>if its ownership was transferred to a third-party for light industrial uses within three years of it being closed for the 2021 MMP operations.</u> "
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	120	Please add "and up to" before "5-foot-thick", replace "peat" with "organic soil", and strike "silt and clay" to avoid overstating the extent and nature of the organics layer, and implicitly acknowledge that loose sand is also a potential weak material by avoiding over specifying "silt and clay"	GEO	Edit has been made in Section 4.2.2.2: "The TSF and TSF Buttress areas include a discontinuous, <u>and up to</u> , 5-foot-thick layer of peat <u>organic soil</u> which would be removed along with topsoil and other potentially compressible/weak silt and clay soils encountered during construction."
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	121	"The presence of the buttress would enhance the overall tailings embankment stability by providing significant additional resisting mass (70 million tons) to resist tailings embankment deformation in static or earthquake conditions ". Please correct; should be 81 million short tons.	GEO	Edit has been made in Section 4.2.2.2: "The presence of the buttress would enhance the overall tailings embankment stability by providing significant additional resisting mass (70 <u>81</u> million tons) to resist tailings embankment deformation in static or earthquake conditions."
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	122	To aid understanding by defining FOS before it is used, and to correctly define design criteria and the analysis cases (standalone dam, or dam with buttress/loss of containment) which were incorrect in the SDEIS, please strike the paragraph beginning with "Slope stability analyses were performed..." and insert the following two paragraphs instead, below the paragraph beginning with "The term "factor of safety" is used... ":	GEO	The proposed narrative changes are a better explanation of the latest stability results based on Tierra Group 2021. Edit has been made.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>Based on IDAPA criteria, FEMA guidance, and industry best practice, Perpetua Resources adopted the Maximum Credible Earthquake (MCE, roughly the 10,000-year event) as the design seismic event for the TSF embankment on a standalone basis. That is, the standalone dam would have a minimum factor of safety of 1.0 for the MCE without taking any credit for the presence of the buttress, even though some amount of buttress would always be present.</p> <p>Slope stability analyses were performed for static, or normal loading conditions, and for pseudo static conditions, representing earthquake loading conditions. The TSF embankment and TSF Buttress were analyzed to determine factors of safety for two potential failure surfaces: 1) full height failure of the downstream slope of the TSF Buttress such that the failure surface intersects the TSF dam crest and thereby causes a potential loss of tailings or water containment; and 2) TSF dam failure, similarly intersecting the crest, but assuming the buttress was not present. Analyses were developed for a variety of events up to and including the design event (the MCE). Results for static conditions, the 2,475-year event, and the MCE are reported in</p>		
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	123	The numbers in the table are confusing and do not match the cases in the RFAI-116 response, from 4/20/2021, which presented the ModPRO2/MMP results, and do not properly reflect the facility design criteria (MCE for standalone dam). Tierra Group 2021 (in response to RFAI-116) would be the proper citation for FOS values to tabulate; Tierra Group 2017 discusses methodology but the results therein are for the PRO configuration. The dam with the buttress has a static FOS ranging from 4 to nearly 6. The standalone dam is around 2 but always more than 1.5. Buttress face (a closure/reclamation stability question not a dam safety question) is above 1.5, but was not included here. Please replace Table 4.2-1 with the corrected table provided in the comment letter, including striking table footnote 1.	GEO	Edits to Table 4.2-1 have been made to incorporate the latest stability results from Tierra Group 2021.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	124	<p>Please correct this paragraph to reflect updated values and updated references for comment above, and consider deleting most of it (everything after "NEPA analysis.") in favor of tabulated values, as the remainder of the paragraph is largely redundant with content above. A potential replacement paragraph is below (without preferred deletion): Based on the slope stability analysis of the proposed design of the TSF dam (Tierra Group 2017, 2021), failure of the TSF embankment from a seismic event is considered to have extremely low probability – less than, and likely far less than, 1 in 10 million annually. Therefore, analysis of failure-related environmental effects is not included in this NEPA analysis. The pseudo-static (i.e., earthquake load) factor of safety for the TSF embankment with the downstream design and buttressing has been calculated for the design earthquake event and selected smaller events covering a range of potential earthquakes possible at the site. At TSF complete build-out, the pseudo static Factor of Safety for the 2,475-year event would be 3.61, more than three times the minimum earthquake load Factor of Safety 1.00, per IDAPA Section 37.03.0. For the MCE (design event) at full build-out and post-closure, the Factor of Safety would be 2.05. The MCE event has a much longer return period (approximately 10,000 years), meaning there is a lower probability of occurrence than the 2,475-year return period earthquake, and results in higher peak ground acceleration (see Section 3.2, for information on peak ground acceleration).</p> <p>Additionally, at complete build-out of the TSF, the static load Factor of Safety would be 5.85, which is well above the minimum required static</p>	GEO	<p>Edits have been made to correlate with the Tierra Group 2021 stability results.</p> <p>Replaced paragraph starting with "Based on the slope stability analysis . . ." with the following version: "Based on the slope stability analysis of the proposed design of the TSF dam (Tierra Group 2017, 2021), failure of the TSF embankment from a seismic event is considered to have extremely low probability – less than, and likely far less than, 1 in 10 million annually. Therefore, analysis of failure-related environmental effects is not included in this NEPA analysis. The pseudo-static (i.e., earthquake load) factor of safety for the TSF embankment with the downstream design and buttressing has been calculated for the design earthquake event and selected smaller events covering a range of potential earthquakes possible at the site. At TSF complete build-out, the pseudo static Factor of Safety for the 2,475-year event would be 3.61, more than three times the minimum earthquake load Factor of Safety 1.00, per IDAPA Section 37.03.0. For the MCE (design event) at full build-out and post-closure, the Factor of Safety would be 2.05. The MCE event has a much longer return period (approximately 10,000 years), meaning there is a lower probability of occurrence than the 2,475-year return period earthquake, and results in higher peak ground acceleration (see Section 3.2.4.6, for information on peak ground acceleration). Additionally, at complete build-out of the TSF, the static load Factor of Safety would be 5.85, which is well above the minimum required static Factor of Safety.</p>
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	125	"Effects would range from temporary (e.g., minor damage that is easily reparable) to permanent (e.g., lateral displacement at fault crossings)". Please remove example; there are no active faults crossing mine facilities as this implies.	GEO	Edit has been made. Sentence starting with "Effects would range . . ." now reads as follows: "Effects to operating facilities would be range from temporary as any damage would be immediately repaired. (e.g., minor damage that is easily reparable) to permanent (e.g., lateral displacement at fault crossings) "
Alan Haslam (Vice President, Permitting, Perpetua	19325	126	The language "Impacts would be reduced to moderate intensity effects through incorporation of existing geotechnical design standards..." coupled with the previous sentences' characterization of impacts as "high-intensity" or "permanent" implies incorrectly that this impact reduction is in some doubt. We are designing to current codes or above. If the effects are reduced to "moderate" then the previous sentences	GEO	Edits have been made to better correlate with the impact descriptions in prior sentences. "Impacts would be reduced to moderate intensity effects through incorporation of existing geotechnical design standards, and building code standards, as well as construction quality control during construction, operations, and maintenance activities and surveillance."

Resources Idaho, Inc.)			should discuss "Potential effects" not just "Effects" when referring to intensity or duration of effects without application of design standards or other mitigation measures.		
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	5	<p>Comments for this resource area are limited to Section 4.2 and include several minor technical clarifications. Though limited in number, comments on the tailings storage facility (TSF) embankment and TSF Buttress are important, and additional information is provided here and in Attachment A that will be useful in addressing comments.</p> <p>Information presented in the SDEIS Table 4.2-1 is discussed below, and a table with revised values is provided for consideration and inclusion in the FEIS. The following paragraph provides the reasoning for these proposed revisions: On pages 4-17 through 4-19 of Section 4.2.2.2, there are a number of updates and clarifications needed related to TSF design criteria and factors of safety. Most importantly, the section misstates the TSF dam seismic design criteria, which is the Maximum Credible Earthquake (MCE) not the 475-year. This seems to be a carryover from the Plan of Restoration and Operations (PRO) where the 475-year criterion was intended to refer to certain short-lived interior impoundment slopes covering rocky hillsides, not the dam itself. As stated in the 2020 Feasibility Study cited in the response to Response for Additional Information (RAI)-116 (April 20, 2021), Perpetua Resources has since adopted the 2,475-year event for evaluation of those slopes, while retaining the MCE for all phases of the dam on a standalone basis (i.e., without accounting for the additional stability added by the Buttress). Additionally, the reported geotechnical factors of safety in the SDEIS do not match those previously furnished for the 2021 Modified Mine Plan (MMP), also in RAI-116, and may be leftovers from the PRO configuration of the Buttress. Suggested changes are included in Attachment A, with changes to Table 4.2-1 noted below. Table 4.2-1 as presented in the SDEIS: Proposed Revisions to SDEIS Table 4.2-1:</p>	GEO	Corrections and edits have been made as described in preceding comments/responses.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	165	Avalanche and Avalanche Mitigation Although the SDEIS addressed some of the previous comments regarding assessment and identification of avalanche terrain along the proposed access routes, there remain significant issues because the current analysis: 1. Mischaracterizes avalanche hazard between the proposed access routes and within the mine site; 2. Underestimates the frequency and extent of avalanche control work necessary to maintain safe ingress and egress during all phases of proposed mining operations; 3. Fails to address direct, indirect, and cumulative effects to forest resources resulting from avalanche mitigation measures and an avalanche control program; and 4. Underestimates annual winter precipitation along the proposed Burntlog Route.	GEO	Specific comments raised in this summarization are addressed in other comment categories. See responses to comments 17634.169, 17634.170, 17634.172, 17634.173, and 17634.176. No further response required here. General in nature or position statement.

Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	168	<p>Corrections to descriptions in SDEIS Chapter 3</p> <p>The SDEIS should accurately describe the affected environment. Section 3.2.4.7 cites a document by the Idaho Office of Emergency Management to explain avalanche formation. This document contains misleading information regarding avalanche formation.202 Rather, this section should cite sources widely accepted by the avalanche industry, such as documents produced by the Canadian Avalanche Association or the American Avalanche Association. On page 3-27, the SDEIS says: “Avalanches occur on slopes averaging 25 to 50 degrees, with the majority on slopes between 30 and 40 degrees, and several avalanche hazard areas occur within the analysis area (Figure 3.2-5).” Instead, this should read: “Avalanches occur on slopes averaging 25-55 degrees, with most slab avalanches occurring on slopes between 30 and 45 degrees, and several avalanche hazard areas occur within the analysis area (Figure 3.2-5).”</p> <p>The next sentence and paragraph state: “Avalanches are triggered by natural seismic or climatic factors such as earthquakes, thermal changes, rainfall, and blizzards, or by human activities (Idaho Office of Emergency Management 2018). The most common types of avalanches are loose-snow and slab avalanches. A loose-snow avalanche is composed of dry, fresh snow deposits that accumulate as an unstable mass atop a stable snow and slick ice sublayer. A loose-snow avalanche releases when the sheer force of its mass overcomes the underlying resistant forces of the cohesive layer. A slab avalanche generally is composed of a thick, cohesive snowpack deposited or accumulated on top of a light, cohesion-less snow layer or slick ice sub-layer. At the starting surface or top of the slab, a deep fracture develops in the slab of well-bonded, cohesive snow. A slab avalanche release is usually triggered by turbulence or impulse waves.” SDEIS at 3-17.</p> <p>This section should be changed to read:</p> <p>A combination of variables, including weather, and snowpack and terrain characteristics, contribute to the formation of avalanche conditions. The most common types of avalanches are loose snow and slab avalanches. Loose snow avalanches occur when slope angle exceeds the sheer strength of surface snow to resist downslope motion. As the surface snow moves downslope it may entrain subsurface snow, increasing the mass and destructive potential of the loose snow avalanche. Wet loose snow avalanches triggered by melting due to warming by the sun or rainfall on the snowpack are generally more massive, and therefore have a greater destructive potential, than dry ones.</p> <p>Slab avalanches consist of a cohesive layer of snow (the slab) overlying a thinner, weaker layer of snow, sitting atop a bed surface (either the ground or another cohesive layer of snow). When the weight of the overlying cohesive layer of snow exceeds the shear strength of the weak layer, the weak layer will begin to fail. A slab avalanche is triggered when the rate of failure in the weak layer is fast enough for fracture to occur, causing the slab to move downslope. Slab avalanches can be triggered naturally by loading new snow, wind deposited snow, or rainfall to the snowpack, cornice fall, warming air temperatures, or earthquakes. Artificial triggers that affect the rate of failure in the weak layer, which can lead to fracture and release of a slab avalanche include skiers, snowmobilers, and explosives. Slab avalanches are typically more destructive than loose snow avalanches because they are more massive and thus result in larger, farther running avalanche events.</p> <p>Additionally, the sentence immediately following Table 4.6-1 (SDEIS 4-98) should be changed to read: “Avalanche risk abatement via explosive methods would be implemented for the SGP. Explosives would be used at higher elevations in the starting zones of the potential avalanche paths to trigger avalanches.”</p> <p>The “with minimum impact” phrase should be omitted because it is confusing and does not describe why explosives are delivered to the starting zones, which is because that is where avalanches can be initiated.</p>	GEO	<p>The suggested edits in Section 3.2.4.7 have largely been adopted to replace the existing paragraph with a new one.</p> <p>Replaced the paragraph in Section 3.2.4.7, beginning with, "The most common types..." with the following: "A combination of variables, including weather, and snowpack and terrain characteristics, contribute to the formation of avalanche conditions. The most common types of avalanches are loose snow and slab avalanches. Loose snow avalanches occur when slope angle exceeds the sheer strength of surface snow to resist downslope motion. As the surface snow moves downslope it may entrain subsurface snow, increasing the mass and destructive potential of the avalanche. Wet loose snow avalanches triggered by melting due to warming by the sun or rainfall on the snowpack are generally more massive, and therefore have a greater destructive potential, than dry ones. Slab avalanches consist of a cohesive layer of snow overlying a weaker layer of snow. When the weight of the overlying cohesive layer of snow exceeds the shear strength of the underlying weak layer, the weak layer may fail causing the slab to move downslope. Slab avalanches can be triggered naturally by loading of new snow, wind deposited snow, or rainfall to the snowpack, cornice fall, warming air temperatures, or earthquakes. Artificial triggers that can lead to fracture and release of a slab avalanche include skiers, snowmobilers, and explosives. Slab avalanches are typically more destructive than loose snow avalanches because they are more massive and thus result in larger, farther running avalanche events."</p>
Bonnie Gestring (Northwest Program Director,	17634	169	<p>The SDEIS mischaracterizes avalanche hazard between the proposed access routes</p> <p>The SDEIS finds that because 38 avalanche paths exist along the Burntlog Route but 94 avalanche paths exist along the Johnson Creek Route, there is a reduced risk to “hazardous materials transport, and public health and safety transportation risks during operations” along the Burntlog Route.206 However, the</p>	GEO	<p>Description of the AHI information that is included in the DAC (2021) technical report has been added to the Avalanche subsection of Section 4.2.2.2 in the Final EIS. The conclusions of the relative avalanche risk along the two access road alternatives described by DAC (2021) and used in the SDEIS have been edited to include the AHI information. Narrative has also</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Earthworks) and seven others			<p>number and size of potential avalanche paths is not the sole basis to determine which route has “less susceptibility” to risks associated with avalanche hazard. Although Dynamic Avalanche Consulting, Stibnite Gold Access Roads: Snow Avalanche Hazard Assessment For Access Roads (Aug. 2021) (herein “DAC (2021)”), assesses the Avalanche Hazard Index (AHI) for each route, the SDEIS makes no reference to it—except in a table of acronyms at the end of the document. SDEIS at 7-55. This error should be corrected.</p> <p>“The AHI is used to determine how serious avalanche problems are to allow comparisons of the avalanche risk to different roads to establish priority areas, to determine appropriate level of avalanche risk management, and to show where control measures have the greatest effect.” DAC (2021), at 39. AHI is a risk assessment tool that considers both exposure and vulnerability of moving and waiting vehicles to avalanches. This is a well-established industry metric to assess and quantify avalanche risk to roadways. Unlike the SDEIS’s conclusion that number and size of potential avalanche paths renders one route more hazardous than another, AHI takes into account a variety of variables, including frequency of avalanche occurrences, total length of highway exposed to avalanche terrain, traffic volume and speed, and type of vehicle traveling the road.</p> <p>Of the 38 avalanche paths identified along the Burntlog Route from Warm Lake to the mine site, 31 are high frequency paths capable of producing D2 and D3 avalanches with one-to three-year return intervals. SDEIS 3-26. Excluding the three paths capable of D3 avalanches every three years on the grade from Warm Lake to Landmark, one path (BLK-7) along the Burntlog Route is anticipated to produce D3 avalanches every three years. SDEIS 4-15. Notably, there are no historical avalanche observations between Black Lake summit and the mine site. DAC (2021), at 6.</p> <p>There are 94 avalanche paths identified along the Johnson Creek Route from Warm Lake to the mine site. SDEIS 3-27. Of these, 31—yes, the same number as the Burntlog Route—are high frequency paths capable of producing D2 and D3 avalanches with a one- to three-year return interval. DAC (2021), at 78. Five can produce D3 avalanches every three years, and four are capable of and have been observed to produce D4 avalanches. The estimated return interval for D4 avalanches is thirty years.</p> <p>Although more confidence exists in the potential for these paths to produce D4 avalanches because of recent observations, these are low frequency occurrences.</p> <p>Frequency is defined as the anticipated number of avalanches per year that will reach or exceed a particular location. As distance from the starting increases, frequency decreases. Thus, in valley-bottom locations like the Stibnite Road, D4 events occur less often. DAC (2021).</p> <p>Comparing the two proposed access routes in this manner shows that the number of high frequency paths are equal. It also shows that of the identified avalanche paths, the Johnson Creek Route has four more avalanche paths capable of producing D3 avalanches every three years than the Burntlog Route. The AHI calculated for the routes captures this difference by concluding that each route is within the moderate hazard category and differs by less than a value of six on a hazard index that can range from 0 to well over 150. Even though there is little difference in risk to vehicles being struck between the two routes, the SDEIS considers only number and size, but not frequency or other variables that are critical to assessing potential risk that vehicles traveling these roads will be struck by an avalanche.</p> <p>Moreover, several assumptions made for the Burntlog Route may increase the AHI. This makes that route equally or even more hazardous than the Johnson Creek Route. Because the Burntlog Route travels for 30 miles between 7000- and 8600-foot elevation, it “will be subject to more wind effects and wind-drift potential,” DAC (2021), at 41, and higher snowfall amounts than the Johnson Creek Route, which travels mostly between 4800- and 6500-foot elevation. DAC (2021), at 13. The SDEIS fails to consider adverse road conditions that will result from managing a resource road above 7000 feet in this area. The significant elevation and steepness differences between the routes must be assessed because claiming the Johnson Creek Route has “higher potential for increased trucking accidents and greater spill risk,” from avalanches fails to account for known terrain and weather characteristics adversely affecting driving conditions along a significant portion of the Burntlog Route. See SDEIS, at ES-13.</p>		<p>been added to clarify that once the Burntlog Route is constructed, mine-related traffic use of the Johnson Creek Route would cease.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>Putting aside Warm Lake Summit, which is common to both routes, the Burntlog Route includes at least three steep climbs (or descents depending on travel direction). In particular, the section that switchbacks into the Black Lake cirque and then climbs toward the Old Thunder Mountain Road is not only above 8000 feet but also the section of road most exposed to avalanche hazard. Decreased traffic speed in this area, which is where 13 one-to-three-year D2 and D3 avalanche paths are located, due to adverse winter travel conditions would increase Burntlog Route's AHI because traffic speed would necessarily decrease below the assumed 25 mph in DAC (2021). It is also worth noting that an Environmental Design Feature proposed by the Forest Service to protect water resources, wetlands, and fish is to maintain an adequate snow floor over the gravel road surface. The effect on vehicle speed of this EDF must be evaluated with respect to the AHI to ensure that appropriate vehicle speed input variables are used in assessing AHI.</p> <p>In addition, unlike the Johnson Creek Route, the frequency and size of the 13 one- to three-year D2 and D3 avalanche paths along the Burntlog Route have no history of observation. No road has ever been constructed across them, which would alter topography, potentially destabilize starting zones, and result in increased avalanche frequency. Any increase in frequency and/or size would result in an increase in AHI. Indeed, even though DAC (2021) highlighted recently observed avalanche activity from four north facing paths along a 1.4-mile section of the Stibnite Road, its correlation with recent fire activity, and the "serious hazard" these paths present because of terrain characteristics, the AHI assessment found little hazard difference between the proposed routes. And none may exist with small changes in the assumptions relative to each route. The SDEIS should not assume, without considering AHI, that the Burntlog Route is less safe with respect to avalanches than the Johnson Creek Route.</p> <p>DAC (2021) notes that as the number of vehicles decreases, so does the relative difference in AHI between the two routes. DAC (2021), at 42. The SDEIS fails to consider reducing the overall number of vehicle trips to reduce AHI because the SDEIS fails to include any discussion of AHI. The corollary is that an increase in vehicle traffic on a particular route increases the AHI, which increases the relative difference in AHI between the routes. The SDEIS fails to consider non-mine site traffic that may use or be allowed to use the Burntlog Route when access through the mine site is closed because of public safety hazards. The SDEIS also fails to consider an increase in the number of vehicle trips for winter/early spring snow plowing and road maintenance. In fact, DAC (2021) states that "[w]ithout further detailed information on [Winter Average Daily Traffic] versus [Annual Average Daily Traffic] volumes, [the Specialist Report] default[s] to the equivalent [Annual Average Daily Traffic] volume for" all phases of mining operations. DAC (2021), at 41. This assumption fails to account for the increased traffic needed for snow plowing and maintenance/avalanche control work, which is especially problematic because these activities would occur when avalanche conditions are more likely to be present, i.e., during winter storms, wind events, and other-related phenomena like rain on snow events that cause deteriorated road conditions. To be very clear, again, adverse winter driving conditions decrease vehicle speed and therefore increase AHI. These unaccounted for variables not only increase the number of vehicles using the Burntlog Route but also may decrease vehicle speed at precisely the time when avalanche conditions are most prevalent. Consequently it seems likely that the AHI for the Burntlog Route is significantly underestimated.</p> <p>The SDEIS is ambiguous about whether under the 2021 MMP the Stibnite Road between Yellow Pine and the mine site would be maintained year-round to ensure two means of access to the mine site. If this is the case, re-assessing AHI to also include public use of this section of road is necessary. In fact, Perpetua's own avalanche consulting firm has recommended that both routes be available because of the potential that one or the other would be closed due to adverse weather/driving conditions and avalanche conditions. In this case, avalanche mitigation would need to occur along both routes, not just the Burntlog Route, to maintain mine site access when the Burntlog Route is impassable or closed. Winter weather conditions that close the Burntlog Route may necessitate maintaining the lower elevation Johnson Creek Route to achieve anticipated time frames of the various phases of mining activities and ensure ingress/egress to the mine site is available in case of emergencies during blizzards or other weather events that preclude use of aircraft. The SDEIS should address or at least clarify this issue.</p>		

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	170	SDEIS should address or at least clarify this issue. Finally, the SDEIS fails to point out that the miles of road affected by high frequency avalanches for both routes are nearly identical (3.1 miles for the Burntlog Route and 3.0 miles for the Johnson Creek Route). Instead, the SDEIS highlights that 8.0 miles of the Johnson Creek Route have some potential to be impacted by avalanches as compared with 4.5 miles for the Burntlog Route. This comparison does not consider frequency or AHI.	GEO	Description of the AHI information that is included in the DAC (2021) technical report has been added to the Avalanche subsection of Section 4.2.2.2 in the Final EIS. The conclusions of the relative avalanche risk along the two access road alternatives described by DAC (2021) and used in the SDEIS have been edited to include the AHI information.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	171	In sum, the SDEIS should assess the AHI by including all traffic (mine and public) using all mine access routes to avoid erroneous conclusions, such as “[t]he Burntlog Route would avoid environmental and human health and safety risks associated with the Johnson Creek Road which passes through identified areas for avalanches, landslides, and floods.”	GEO	The AHI information included in the DAC (2021) report has been added to the Avalanche subsection of Section 4.2.2.2 of the Final EIS. The descriptions of the relative avalanche risks posed by the two access road alternatives, including consideration of the AHI information have been edited as necessary. It is not an incorrect statement that the Burntlog Route would avoid the risks posed by the Johnson Creek Route because they are mutually exclusive of each other once the Burntlog Route is operational. But the Johnson Creek Route risks would be present during construction and this fact has been clarified in the Final EIS.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	201	Up-to-date geologic hazard assessment not completed on existing Johnson Creek or Stibnite roads Several major slides and debris falls have occurred recently on the Stibnite road, and several high hazard locations are known on the Johnson Creek (and at least one on the upper Warm Lake road near the summit). These roads will be used no less than two years during construction and potentially in the 2021 MMP alternative for the life of the project. Yet full reconstruction will not occur on these roads according to the current plan. The most recent geologic hazard assessment cited in the SDEIS is STRATA, 2016. It is unreasonable to assume that conditions remain the same six years after the most recent assessment. Further, we recommend that the Forest Service require a new geologic hazard assessment every two years at a minimum through the life of the project.	GEO	The geologic hazards areas, along the two proposed access road alternatives was updated by AECOM in 2020 (AECOM 2020c). The relative numbers of these hazards along the two access roads discussed in the SDEIS, and shown on Figure 3.2-6, are from this more recent analysis.
David Chambers	17634-A	7	2.4.6.2 Underground Exploration In the SDEIS, it is noted: “Underground exploration activities could occur for the SGP throughout the life of the mine, such as the newly-discovered Scout Prospect, a 1-mile, downward-sloping tunnel... Approximately 100,000 tons of rock would be excavated from the decline.” Underground exploration could potentially impact water quality and quantity, and involve the surface disposal of rock with as-yet defined geochemical properties, which could affect the type and level of contaminants that leach from this rock. Information on the predicted water quality and quantity impacts, the geochemistry of the waste that require surface disposal, and the closure plans for the underground workings should be presented in the SDEIS. If an exploration project that included a 1-mile tunnel producing 100,000 tons of waste rock were proposed as an independent project, it would warrant an EIS. Yet the only information provided about this project is limited to the 10 sentences that constitute Section 2.4.6.2. The lack of information, data, and analysis in the SDEIS is insufficient to authorize an activity of this scope. In addition, the Feasibility Study (M3 2021) contains an entire Section, 9.8 Potential High-Grade Underground Mining Prospects, that discusses 5 separate underground prospects in the immediate vicinity of the Stibnite Gold Project (including Scout), consisting of 14 pages of information. The two pages of information on the Scout Prospect in the Feasibility Study is devoted mostly to the mineral resource potential, but it is noted that Scout lies in the Scout Valley Fault Zone, and that the potential underground target is in the range of 2-5 million tons.	GEO	The handling of the development rock from the underground exploration facilities is described in Section 2.4.6.2 of the SDEIS. This rock would be used for surface pad construction, ore feed, or development rock used in the TSF Buttress. The proposed closure plans for the underground exploration tunnel are described in Section 2.4.7.3. The water quality impact analyses for these facilities are described in Section 4.9.2.2. The potential scale of environmental effects of the underground exploration facilities are considered well within that of the rest of the Proposed Action so this NEPA analysis is considered sufficient for the underground exploration facilities. If additional underground ore resources are discovered such that significant changes would be proposed in the future to develop these resources in addition to those already included in the 2021 MMP, the Forest Service would evaluate what additional NEPA analysis is required.
David Chambers	17634-A	11	4.2.2.2 2021 MMP – Tailings Storage Facility and TSF Buttress The stability analysis of the tailings dam is discussed in this section. The analysis is summarized in Table 4.2-1 Calculated Factors of Safety for the TSF Embankment and TSF Buttress. The analysis is based on a study performed for the original project as proposed by Midas Gold (Tierra Group 2017). The	GEO	Additional slope stability analyses have been performed for static, or normal loading conditions, and for pseudo static conditions, representing earthquake loading conditions (Tierra Group 2021). The TSF embankment and TSF Buttress were analyzed to determine factors of safety for two potential failure surfaces: 1) full height failure of the downstream slope of the TSF Buttress such that the failure surface intersects the TSF dam crest and

			<p>Tierra Group study uses the Site-Specific Seismic Hazard Analysis performed by URS (2013) as the basis for its seismic stability calculations. That study has been superseded by the Site Specific Seismic Hazard Assessment (Golder (2021)). Even though the Golder study reduces the calculated peak ground acceleration that it predicts could be experienced at the site, it is not clear that the spectral accelerations associated with the lower peak ground acceleration are less than those associated with the 2017 Tierra Group peak ground acceleration. The issue of spectral acceleration differences from the Tierra Group is not addressed by Golder. In addition, Golder notes that the only bedrock conditions were used for the ground motion conditions in the pseudostatic modeling (Golder 2021, p. 7). The center portion of the dam will be constructed on alluvial/glacio-fluvial valley sediments, with the left and right abutments bedrock (Golder 2021). It is not clear from the Golder-Tierra discussions why pseudostatic modeling is appropriate for a dam with several different foundation conditions, and whether two-dimensional modeling might better reflect the different dam foundation conditions.</p> <p>In addition, the Tierra 2017 analysis, where the current static and seismic factors of safety were developed, did not cite an actual tailings dam design report as the basis for developing the model it used to conduct the pseudostatic analysis. As with the information provided for tailings dam design in the SDEIS, we do not know where the engineering specifications for the dam design come from. It appears that some actual engineering design work has been done, but there is no reference to it. We do not know what specifications have been required, for example the type of fill, and the quality assurance requirements that will be enforced. We do not know what assumptions were assumed in the factor of safety calculations. The level of design information presented for the tailings dam is insufficient to adequately review the dam design information used to calculate the factors of safety.</p> <p>The use of pseudostatic analysis for dam of this size is questionable, even though pseudostatic analysis is often used for tailings dams. One of reasons for its wide acceptance is that it is less expensive to run than a two dimensional model. Although widely accepted, there are a number of long-recommended cautions about using pseudostatic modeling.</p> <p>In 2005, the Federal Energy Management Agency published a report titled “Federal Guidelines for Dam Safety Earthquake Analyses and Design of Dams” (FEMA 2005). These guidelines, which are still current, contain a thorough discussion of dam modeling techniques. It has this to say about pseudostatic models:</p> <p>“A pseudostatic analysis (sometimes called seismic coefficient analysis) should only be considered as an index of the seismic resistance available in a structure not subject to build-up of pore pressure from shaking. It is not possible to predict failure by pseudostatic analysis, and other types of analysis are generally required to provide a more reliable basis for evaluating field performance.” (FEMA 2005, p. 35) and; "Pseudostatic methods are generally discouraged and should only be used for screening from further consideration those dams where a seismic stability failure is highly improbable. ... Dynamic timehistory analyses are used to determine the displacements and stresses experienced by the dam and foundation. Evaluation of the results is used to determine if there is a risk of a stability failure.” (FEMA 2005, p. 38) Cost is a paramount consideration for a tailings dam. A tailings dam does not produce revenue for a mine, it is an operational cost. Mines are always looking for ways to minimize the cost of waste disposal. The only reason for using upstream-type and centerline-type dam construction is to lower the cost of dam construction. Tailings dams are designed by engineering consulting companies, not by the mining companies themselves. As consultants, engineering consulting companies want to minimize cost to their clients. It is in their economic interest to do so. While this does not mean they would adopt dangerous practices, it does mean that lacking clear guidance to utilize the safest practices in the design, construction, operation, and closure of tailings dams, “site-specific” considerations do often lead to the employment of what would otherwise be considered suboptimal practices. Examples of these suboptimal practices include upstream-type dam construction, the use of saturated tailings impoundment closures to minimize cost, and pseudostatic analysis.</p>		<p>thereby causes a potential loss of tailings or water containment; and 2) TSF dam failure, similarly, intersecting the crest, but assuming the buttress was not present. Analyses were developed for a variety of events up to and including the design event (the MCE). Results for static conditions, the 2,475-year event, and the MCE are reported in the Final EIS as a revised Table 4.2-1.</p>

Samuel Penney (Chairman)	19396	335	<p>Multiple avalanches and landslides have caused extensive damage to the McCall-Stibnite Road over the last decade. Similar events are likely to occur again, not only for the McCall-Stibnite Road, but also for sections of the proposed Burntlog Route and Johnson Creek Route where roads are adjacent to steep terrain.</p> <p>Wildfires, new road construction, pit highwalls, devegetation of the Project site will cause additional mass wasting events that impact streams with ESA-listed fish species. The FEIS needs to analyze risk of landslides using more rigorous methods, such as landslide susceptibility or landslide hazard modeling.</p>	GEO	The baseline condition of geologic hazards potentially affecting the 2021 MMP is described in Section 3.2.4.7 of the SDEIS. The potential geologic hazards along the proposed Johnson Creek Route Alternative are described in Section 4.2.2.3 of the SDEIS. Effects to topography caused by the 2021 MMP are described in the Topography subsection of Section 4.2.2.2. The potential impacts of geologic hazardous to the 2021 MMP are described in the Geotechnical Stability subsection of Section 4.2.2.2. It is disclosed that these natural features could potentially be destabilized by the construction and operations but that these impacts would be minimized by incorporating designs, construction quality, operational maintenance, and monitoring to deal with any geotechnical instability impacts. The potential risk of any one of these locations is site specific and dependent on the final designs. The impact of any instability is described as being localized and are expected to be short-term and moderate intensity.
Samuel Penney (Chairman)	19396	336	<p>Additionally in the FEIS, the location of potential mass wasting areas should be described and their risks to ESA- listed fish species fully addressed.</p>	GEO	Geologic hazards for the operations area and access road alternatives were described in Section 3.2.4.7 of the SDEIS. The potential impacts of landslides and rockfall on the operations and access road alternatives are described in Sections 4.2.2.2 and 4.2.2.3. These sections describe that the impacts of geotechnical instability are expected to be localized and that unstable areas would be addressed by stabilizing designs during construction activities. Therefore, effects of these landslide and rockfall areas on fish habitat is expected to minor. Impact of sediment and turbidity on aquatic habitat is present in Section 4.12.2.2 of the Final EIS.
Samuel Penney (Chairman)	19396	339	<p>Stochastic Events Not Fully Analyzed</p> <p>In addition to roads, the SDEIS does not adequately address climate change and blasting with explosives as it relates to stochastic events near Endangered Species Act-listed fish at the Project site. The SDEIS only states that "Current climate change trends, such as increased heavy precipitation events and more precipitation falling as rain instead of snow, could lead to increased soil erosion and change in land cover, which could potentially impact slope stability in the analysis area. Damage due to seismic activity in the area also could be exacerbated by climate-induced instability in the analysis area." However, the SDEIS omits any analysis of this potential instability or the increased risk of erosive events in light of climate change</p>	GEO	Current sediment loading in the area streams is caused by erosion of natural and mining-disturbed surfaces in the proposed operations area. Section 1.3 describes that significant areas of legacy mining disturbances adjacent to the local streams will be reclaimed under the ASAO to reduce impacts to surface water quality. Section 2.4.5.6 describes that other legacy mining wastes, which are current sources of surface water impacts, would be removed during construction and early operations. Section 2.4.5.10 of the SDEIS describes how surface water flow through the operations area would be managed to avoid erosion of the stream channels. Of particular note is the description of the stream stabilization and restoration of the Blowout Creek watershed, which is a legacy source of much stream sediment in the past. Closure and reclamation of the proposed facilities is described in Section 2.4.7. The disturbed surfaces and stream channels would be reclaimed in a manner to control erosion and transport of sediment from the area. Baseline erosion and sediment transport conditions are described in Section 3.9.4.4. Section 4.9.2.2 discusses the effects of the proposed mining operations on surface water quality. Contact water derived from runoff over the mine disturbances would be routed to a number of contact water ponds. Management of the water in the contact water ponds would be in compliance with the IPDES stormwater and individual permit requirements for sediment and turbidity control. Narrative related to impacts by sediment and turbidity is presented in Section 4.12.2.2 of the Final EIS. Blasting would occur within the open pits and the underground exploration mine. Any excess water from within these areas directly affected by blasting would be pumped to contact water ponds for management and would not be directly released to area streams. The potential changes from climate change on the affected environment of the Project Area is described in Section 3.4.
Samuel Penney (Chairman)	19396	340	<p>Furthermore, the SDEIS notes that blasting will occur, but does not analyze the increased risk of erosive events. Unfortunately, all stream reaches in the headwaters of the EFSFSR subwatershed are already at unacceptable risk for sediment/turbidity for Chinook salmon, steelhead, and bull trout. The risk of erosive events associated with the Project needs to be analyzed, and synergistic agents such as climate change and blasting should be included in the models.</p>	GEO	Current sediment loading in the area streams is caused by erosion of natural and mining-disturbed surfaces in the proposed operations area. Samuel Penney (Chairman)	19396	341	There is no assessment of geologic hazards on any of the mine access roads, including the existing Warm Lake highway, Johnson Creek road, Stibnite Road, or the newly proposed Burntlog Road. There are landslides, avalanches and mass wasting events on the existing streamside roads nearly every spring. These roads are mostly located on the Idaho batholith, which is granitic, known for decomposing easily, and not being competent or well suited for road bases.	GEO	Geologic hazards for the operations area and access road alternatives are described in Section 3.2.4.7.

Air Quality

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Elizabeth Barnes	6652	10	Table 4.3-3 Why is ammonia not measured in air quality analysis?	AIR	Table 4.3-3 is specific to EPA criteria pollutants. Ammonia is not a criteria pollutant. Hazardous pollutants and Idaho state regulated toxics are discussed in Section 4.3.4.2 and the Air Quality Specialist Report. Ammonia is regulated by the Idaho state air quality Idaho Admin Code 58.01.01.585 - Toxic Air Pollutants Noncarcinogenic increments. The SDEIS air quality analysis determined the ammonia concentration is below the Idaho DEQ screening emission level limit. Additionally, total dry nitrogen deposition is outlined in Section 3.3.4.4 whereby ammonia deposition is a portion of the total Nitrogen. General ammonia deposition is also addressed in that section. The Air Quality Specialist Report Section 6.1.4.1 also discusses this.
Lehrer, Laura	16878	5	The lack of air quality monitoring.	AIR	The USFS agrees that the high emission control factor of greater than 90% is difficult to verify. The facility was issued Idaho Air Quality Permit P2019.0047 that required the facility to develop a Fugitive Dust Control Plan(FDCP) with multiple methods to control dust. Additionally, records are required to be kept. Dust monitoring is required using EPA Reference Method 9 and records are required. The USFS would include additional requirements for monitoring with may include EPA Federal Reference Methods or Federal Equivalent Methods using equipment such as such as Esampler and E-Bam. Additionally, multiple purple air sensors may be deployed to assess periods of high PM2.5 emissions and EPA method 9/method 22 visible emissions monitoring would be part of the monitoring in all mining areas and haul roads that are included in the DSEIS. The operators would keep records of monitoring and dust control plan and using the Idaho DEQ forms for fugitive dust control. This is incorporated in Section 4.3.5 of the Final EIS.
von Lindern, Ian (Founder, Terragraphics International Foundation)	17436	6	TIFO comments include rudimentary material balances for the DEIS and SDEIS Alternatives. Table SD1a contains the Pit-specific and historic waste material COC distributions for Development Rock DR, Ores, and Historic Materials from the SRK (2017) SGP Baseline Geochemical Characterization Report. Tables SD1b and SD1c, combine the COC distributions with mining production estimates from M3 (2014), (2019) and (2021) Stibnite Gold Project Feasibility Technical Study Reports supporting the MoDPRO and MoDPRO2 Alternatives. These Tables contain probability distributions of COC production for mined materials for the DEIS and SDEIS, respectively. Table SD2 summarizes overall	AIR	The commenter submitted quantitative re-evaluation of the chemical characterization data in the 2020 DEIS to prepare elemental material balances for the different ore and waste materials of the operations. However, the elemental material balances are not solely indicative of potential environmental effects or how these effects compare to existing regulatory limits and guidance. These elemental material balances are not typically used in NEPA analyses of proposed mining operations. The impact analyses included in the SDEIS do utilize typically

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>DEIS and SDEIS Pit-mined COC production. Table SD3 summarizes COC production and DR COC disposal for the SDEIS Alternative.</p> <p>The lack of material balances has been noted in several reviews including the DEIS and several IDEQ PTC submittals regarding the SGP. It is unusual that credible material balances are excluded in such complex environmental systems analyses. IDEQ has responded that material balances are “helpful but not required,” and has been unwilling to request SGP to supply the accounting. The Nevada Department of Environmental Protection (NDEP), that regulates the only comparable gold refinery operations in the United States, does require material balances. Despite the Forest Service Air Quality Expert Report 2022 citing the NDEP requirements as exemplary, the Forest Service has not completed material balances for either the DEIS or SDEIS. As demonstrated below, COC sources, concentrations and distribution differ significantly for the DEIS and SDEIS.</p> <p>The Forest Service should require material balances for toxic contaminants in future Supplemental analyses.</p>		acceptable data and methods to predict chemical impacts to environmental media and then compares these projected impacts to existing regulatory requirements and guidance.
von Lindern, Ian (Founder, Terragraphics International Foundation)	17436	14	<p>Arsenic Emission Rates are Underestimated: Use of inappropriate Emission Factors (EF)s in the 2021 MMP combine to significantly underestimate arsenic emission rates in the SDEIS. The most critical EF selections are associated with Mining Fugitive Dust and include underestimated i) arsenic concentrations in Pit roadbeds, ii) silt content in on-site gravel roadbeds, and ii) percent control levels for application of dust suppressants. Each is discussed below.</p>	AIR	The emission factors used are described in Section 4.3.1.2 and were based on regulatory and industry technical documents as detailed further in the Air Quality Specialist Report.
von Lindern, Ian (Founder, Terragraphics International Foundation)	17436	15	<p>Arsenic Dust Concentrations: Fugitive Mining Dusts in the three Pits will reflect the changing arsenic production and concentrations noted in Table SD6. The new 2021 MMP Preferred Alternative analyzed in the SDEIS does not include these changes. The DEIS characterized all Haul Roads using the median concentration of site-wide rock samples of 667 ppm As. The 2021 MMP uses 667 ppm to calculate mining fugitive dust arsenic emissions for Pit Haul Roads and substitutes 90 ppm for “CR: clean rock - used to cap haul roads outside of the pits and DRSFs.” The 2021 MMP modification should have included substituting the Pit-specific arsenic concentrations noted in Table SD6 for in-Pit Haul Roads. This oversight underestimates in-Pit arsenic emissions by 1.3 times for the WEP, 3.4 times for YPP, and 5.2 times for HFP. Table SD7 shows the calculation adjusting for the weighted in-Pit Arsenic concentrations from Table SD6.</p>	AIR	A median arsenic concentration was utilized to assess aggregate dust emissions from Project traffic which travels variable routes depending on the daily mining activity. There would be areas of higher arsenic concentrations and lower arsenic concentrations compared to the median value, but that value is characteristic of the overall distribution.
von Lindern, Ian (Founder, Terragraphics International Foundation)	17436	16	<p>Haul Road Silt Content: Pit Haul Road (HR) Fugitive Dusts are the largest source of total particulate (PM) and arsenic emissions, accounting for 83% of PM as calculated in the 2021 MMP Preferred Alternative. HR PM emissions are grossly under-estimated due to unrealistic assumptions regarding the silt content of the roadbeds and the level of control assumed for dust suppressants.</p> <p>The Forest Service cites USEPA AP-42 guidance as the basis for HR Dust emission estimates. Table 13.2.2-1 from the cited guidance summarizes 272 gravel road samples from 53 sites at 18 different industries. Ten (10) sites and 58 samples were obtained specifically from Haul Roads. Haul Roads silt content ranged from 5.8% to 24%, averaging 11.6%. The minimum mean silt content from any one site was 4.3% for all gravel roads and 5.8% from Haul Roads. Table SD8 summarizes the USEPA AP-42 results for all roads. (USEPA 2022.)</p> <p>The SDEIS uses a 4% silt content, lower than any value observed by the USEPA. The 4% value is referenced to "Soil Resources Baseline Study, Stibnite Gold Project." Reid, Samuel B., Assistant Geology Supervisor, Midas Gold, Inc., April. (Midas Gold 2015). The Appendix to this document notes <75 micron fractions for 28 on-site sieved soil samples, but it is unclear how the 4% value was selected. Although the guidance indicates the importance of locally collected data, the 4% silt content cited by Midas are most relevant to “dirt roads” operating on native soils. The in-Pit Haul Roads at SGP will be constructed from Development Rock crushed gravels from within the Pits and with “CR: clean rock - used to cap haul roads outside of the pits and DRSFs.” The silt content of industrial constructed gravel haul roads is generally designed and maintained at higher levels for stability reasons, as indicated in Table 13.2.2.1 of the AP-42 document (i.e., mean values ranging from 5.8% to 24%). Substitution of 8% and 24%, as a more appropriate range, for roadbed silt content into the Emission Calculations in the</p>	AIR	The silt content of gravel roadways was predicted based on the analysis of site materials as described in the cited baseline report. Therefore, the value was used as characteristic for the site.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			Appendices relied on for the SDEIS, increases uncontrolled PM emissions by 1.6 to 3.5 times, respectively. Table SD9 shows these calculations applied to the On-site Hauling fugitive dust Maximum production scenario in Table SD4 (i.e., 2901.3 tons/yr.).		
von Lindern, Ian (Founder, Terragraphics International Foundation)	17436	17	<p>Particulate Control: The SDEIS also relies on 93.3% particulate control achieved by a combination of chemical dust suppressants and watering. The AP-42 Guidance (AP-42) also discusses the effectiveness of both technologies. As Perpetua’s control strategy relies largely on chemical dust suppressants, it is important to note the following excerpt from AP-42 that concludes: “Past field testing of emissions from controlled unpaved roads has shown that chemical dust suppressants provide a PM-10 control efficiency of about 80 percent when applied at regular intervals of 2 weeks to 1 month” (p 13.2.2-12). This suggests the proposed 93.3% control assumptions are suspect and will more likely range from 80% to 90%. Controlled emissions would be 1.5 - 3.0 times greater at 90% and 80% control, respectively. Table SD9 also shows that using 8% and 24% silt content increases the required PM control from 93.3% to 96.4% and 98.7%, respectively. These values are not achievable even for paved roads.</p> <p>Table SD10 shows combined correction factors for the several emission factors underestimated by IDEQ and accepted by the Forest Service. In combination, correcting for the arsenic concentration and silt content in roadbeds and percent control for dust suppression underestimates indicate that arsenic emissions are likely 7.5 - 33 times greater from the YPP, 14 - 60 times greater for HFP, and 3 - 14 times greater for the WEP, than those estimated in the SDEIS. These changes alone would result in exceedance of cancer risk criteria. Unfortunately, specific calculations of the ambient estimates cannot be developed, as the link to the electronic support documents cited by the Forest Service cannot be accessed.</p>	AIR	The fugitive control management compliance requirements would be rigorous due to the high dust control proposed by Perpetua. The 93.3 percent control has been accepted by IDEQ and adopted for assessment of emissions by the USFS based on the use of chemical suppressants and water application.
von Lindern, Ian (Founder, Terragraphics International Foundation)	17436	18	<p>Airborne Arsenic Carcinogenic Risks Are Underestimated: Carcinogenic risk is determined by appropriately estimating emissions from SGP proposed activities, conducting air quality modeling to estimate ambient air arsenic concentrations and exposures, and comparing the exposures to carcinogenic risk criteria. The analyses the Forest Service relies on understates arsenic impacts in each of these steps. Objective correction of these dilutions results in cancer risks exceeding acceptable levels. These serial dilutions significantly underestimate carcinogenic risk for average conditions. Estimating risk at the average exposure implies half the receptor population has a greater cancer risk. Carcinogenic risk should be evaluated at both mean and reasonable maximum exposures (95th%tile) to ensure protectiveness for the more vulnerable receptor population. Neither the Forest Service, nor IDEQ, has performed responsible risk assessment calculations. This is one basis for the current Administrative Appeal of the PTC. The serial dilutions are described in the following paragraphs.</p> <p>The SDEIS cites a Perpetua consultant’s report (Air Sciences 2021b) that alleges compliance with the 10-6 cancer risk criteria by comparing a calculated maximum equivalent 70-year exposure of 0.00015 ug/m3 arsenic to the 0.00023 ug/m3 standard. These calculations include a number of questionable dilution steps. Nevertheless, as calculated by the Forest Service, this evaluation implies that the 12 years of the 2021 MMP consumes 65% (0.00015/0.00023) of a receptor’s acceptable 70-year lifetime exposure. Appropriate emission rate estimates are critical to estimating carcinogenic risk associated with the Preferred Alternative. Even by the Forest Service analysis, any correction of the EFs resulting in a > 50% (or 1.5 times) increase in arsenic emissions, would result in exceedance of the carcinogenic risk criteria.</p>	AIR	Section 4.3.4.2 describes arsenic air emissions associated with the Project and compares them to acceptable ambient carcinogenic concentrations in SDEIS Table 4.3-13 which shows them to be below the acceptable concentrations Idaho standards (IDAPA 58.01.01.586).
von Lindern, Ian (Founder, Terragraphics International Foundation)	17436	19	<p>Table SD10 summarizes the appropriate correction factors for Haul Road emissions and includes combination factors for As concentration, silt content, and % Particulate Control adjustments.</p> <p>Applying any combination of adjustments >1.5 in Table SD10 would result in excess cancer risk. For example, simply correcting for the minimum increases in arsenic emission rates for the WEP (3 – 14 times) results in airborne arsenic exposures arsenic levels exceeding the applicable carcinogenic risk criteria. That is, 3 x 0.00015 ug/m3 = 0.00045 ug/m3, corresponding to 2 x 10-6 cancer risk. Applying the 14 fold increase indicates a 9.3 x 10-6 cancer risk. Similarly, should either the silt content (1.6 -.3.5) or control level corrections (1.5 – 3.0) apply, excessive cancer risk will result. Correcting for silt content,</p>	AIR	Section 4.3 describes the site data and assumptions utilized to forecast arsenic air emissions and their comparison to acceptable ambient carcinogenic concentrations. The parameter values proposed by the comment were not adopted in the approved air quality modeling.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			percent control and pit-specific concentrations for all Pits, likely increases to concentrations >10-5 risk levels.		
von Lindern, Ian (Founder, Terragraphics International Foundation)	17436	20	<p>Inappropriate Serial Dilution of Exposure Indices: The preceding discussion applies only to underestimated emissions. In addition to diluting emissions, the 0.00015 ug/m3 arsenic chronic exposure cited by the Forest Service was derived using three additional inappropriate dilutions of the air quality modelling results. In total, four levels of inappropriate dilution are: i) the underestimated arsenic emissions, noted above, due to unrealistic particulate arsenic concentrations, roadbed silt content, and control levels; ii) maximum emissions input to the air quality models are five-year averages (not maximums) diluted by different pit production ratios; iii) the predicted model results are diluted by averaging the results of two scenarios, one WEP and one non-WEP related. This averaging incorrectly reduces the WEP maximum annual average by 41%. The Forest Service relies on IDEQ's assertion that this technique is justified on the basis that maximum prediction for the WEP scenarios will not apply during the life of the mine. There are several problems with this reasoning.</p> <p>The five-year average already accommodates this effect. Several of the scenarios are no longer applicable, as the DR repository destinations no longer exist. The adjustments for Pit-specific dust concentrations are much greater for the non-WEP scenarios; and iv) adjusting for the ratio of the 16-year life of the mine to the 70-year lifetime of the receptor dilutes the ambient calculation by an additional 78%. The SGP is not entitled to consume the remaining 54 years of the receptor's 70 year lifetime acceptable exposure during the alleged 16-year life of the mine. (IDEQ 2022b).</p> <p>These serial dilutions are another basis for the IDEQ PTC Administrative Appeal currently under consideration. Correction of these serial dilutions likely increase exposures and cancer risks by an order of magnitude exceeding 10-5 cancer risk criteria.</p>	AIR	Section 4.3 describes the site data and assumptions utilized to forecast arsenic air emissions and their comparison to acceptable ambient carcinogenic concentrations. The alternative assumptions proposed by the comment were not adopted in the approved air quality modeling.
von Lindern, Ian (Founder, Terragraphics International Foundation)	17436	22	<p>On-site Carcinogenic Air and Dust Exposures: All of the air quality analyses are limited to off-site ambient air. On-site air concentrations are likely an order of magnitude higher. In the interest of worker, site resident and visitor health, the Forest Service should estimate on-site airborne arsenic levels and assess the risk of on-site exposures. The high arsenic content of the dusts is also a health concern due to direct contact exposure, incidental ingestion, inhalation, and skin absorption. Arsenic levels in on-site dusts will range from 580 – 10,000 mg/kg. Total arsenic concentration for growth media range up to 3,000 ppm As, justified on the basis of observing vegetation survival on Hecla reclamation sites. These metals concentrations substantially exceed (by 2 – 3 orders of magnitude) health risk screening and CERCLA cleanup levels for occupational, recreational and residential scenarios. On-site workers and visitors will be exposed to concentrations, potentially, orders of magnitude greater than these criteria. Neither Perpetua, nor the Forest Service or IDEQ have publicly disclosed estimated on-site airborne concentrations.</p> <p>In the interest of Public Health protection, the Forest Service should not defer to the IDEQ PTC assertions under Administrative Appeal. The Forest Service should independently perform the emission calculations, air quality modeling, and risk assessment associated with COC releases from this facility. Resulting COC airborne and dust concentrations, both on-site and off-site estimates should be publicly disclosed. Human health risk assessments should be undertaken at mean and Reasonable Maximum Exposures (RME). Soil cleanup criteria should meet CERCLA guidelines.</p>	AIR	On-site carcinogenic air and dust exposures would be regulated under MSHA requirements for mine operation. Therefore, attainment of standards for worker health would be reasonably foreseeable for the Project. Dust monitoring is incorporated into the Final EIS in Section 4.3.5. For further details see response to comment 16878.5.
Kevin Proescholdt	17616	9	* Figure 3.3-2 erroneously omits the Monument Rock, North Fork John Day, North Fork Umatilla, Wenaha-Tucannon, Welcome Creek, Rattlesnake, and Jim McClure-Jerry Peak Wildernesses from the map and fails to label Cecil D. Andrus-White Clouds and Hemingway-Boulder Wildernesses all within the Far Field Boundary.	AIR	Figure 3.3-2 has been revised to add omitted Class II wilderness areas.
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	2	Monitoring for fugitive dust and particulate matter air emissions, assessing airborne arsenic impacts, confirming consistency across proposed state and federal air quality measures, and addressing possible underestimations of mercury deposition.	AIR	As outlined in comment response 16878.5 dust monitoring would be incorporated into the Final EIS as a mitigation measure under Section 4.3.5. Arsenic impacts have been determined for potential sources and compared to the IDEQ acceptable ambient carcinogenic concentrations. Mercury deposition expectations were established using the REMSAD model;

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
					while the data is somewhat dated (2000-2006), it is likely a conservative measure due to more recent regulatory controls.
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	12	Idaho Department of Environmental Quality (IDEQ) Air Quality Permit to Construct (PTC) The DSEIS indicates on June 17, 2022, IDEQ issued a final PTC and Statement of Basis (SOB) stating that the Stibnite Gold Project (SGP) will not require a Title V permit. Further that “[a] determination was made by the State of Idaho that the SGP satisfies the requirements of the PTC program, based on demonstration of the SGP’s potential emissions and controls. This was based on the complete air emissions inventory of stationary sources that was submitted by Perpetua as part of its application to the IDEQ for an air quality permit.” EPA formally commented during the public review process for IDEQ’s draft air quality PTC that the draft PTC did not appear to sufficiently limit annual emissions to allow the SGP to avoid being subject to the Title V and Prevention of Significant Deterioration (PSD) programs and assure compliance with the National Ambient Air Quality Standards. EPA continues to review the final PTC for compliance with the CAA. As a Cooperating Agency for this project’s EIS, EPA shared our March 2022 draft PTC comments with the Forest Service. EPA recommends the FEIS include a summary of EPA’s public comments. EPA is available to meet with the Forest Service and IDEQ, who is also a NEPA cooperating agency, to discuss our concerns and answer any questions.	AIR	This was an inadvertent error. Due to being subject to NESHAP Subpart 7E, a Title V permit is required. The language in the Final EIS has been updated to address this error. The emission controls and enforcement would be outlined in the Fugitive Dust Control Plan to be completed to the satisfaction of USFS prior to construction and other restriction measures throughout the IDEQ permit. It should also be noted that the Final EIS would have generally lower throughputs more representative of typical operating conditions to be incorporated into the Record of Decision. Should the proponent request to increase beyond the proposed throughputs, any change would have to be evaluated and reassessed as appropriate.
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	13	Enclosure of Main Ore Processing Facility and Coarse Ore Stockpile The DSEIS indicates the main ore processing facility building and coarse ore stockpile will be enclosed. EPA notes that IDEQ’s PTC does not include stipulations that the main ore processing facility building and coarse ore stockpile will be enclosed. Given the inconsistency, EPA recommends the FEIS clarify whether the main ore processing facility building and coarse ore stockpile will be enclosed, which EPA supports to reduce dust. If the main ore processing facility building and coarse ore stock will not be enclosed, correct its description throughout the FEIS. EPA also recommends adjusting the assessment analysis to account for the change.	AIR	The Final EIS has been updated under the mitigation measures Section 4.3.5 and corrected to clarify that the facilities would be enclosed.
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	14	Bag House Dust Collectors The DSEIS indicates water sprays and/or bag house dust collectors will be installed at the ore-crushing system and at ore reclaim feeders that deliver ore to the grinding circuit.6 EPA notes that IDEQ’s PTC does not include baghouse dust collectors within the ore-crushing system and at ore reclaim feeders. EPA recommends that the FEIS clarify the measures that will be taken for the SGP, and adjust any inconsistencies in the FEIS, including the assessment analysis to account for the change.	AIR	The Final EIS requires controls as these were accepted by the proponent. Any inconsistencies have been rectified in the Final EIS. All mitigation measures have been added to Section 4.3.5 of the Final EIS.
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	15	Title V Permit Regarding the DSEIS statement “[t]he regulation establishes mercury emissions limitations and work practice standards to control mercury emissions from gold production processes.” EPA recommends evaluating if this regulation would require a Title V permit for the SGP. If so, EPA recommends adding the following sentence in the same paragraph “This regulation also requires that the SGP obtain a Title V permit. See 40 CFR 63.11640(d). This requirement is separate and independent from whether a Title V permit is needed based on the project’s potential air emissions.”	AIR	This was an inadvertent error. Due to being subject to NESHAP Subpart 7E, a Title V permit is required. The language in the Final EIS has been updated to address this error.
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	16	Fugitive Dust and Particulate Matter (PM) Monitoring Table 2.4-12 in the DSEIS indicates “[t]he Proponent will prepare a dust mitigation plan with appropriate schedule or triggers for control deemed adequate by IDEQ to achieve the level of control of 93 percent of dust (as submitted in the proponent’s draft application for Permit to Construct from IDEQ). Alternatively, the proponent could employ particulate matter or opacity monitors deemed adequate by IDEQ and the Forest Service and immediately apply water or chemical dust control when PM or opacity monitors reach levels within 10 percent of the threshold determined by IDEQ.” Since the final PTC has been issued by IDEQ, EPA recommends changing the reference to the draft application to a reference to the PTC for the FEIS. PTC permit condition 2.6 requires the proponent to develop and maintain a Fugitive Dust Control Plan (FDCP) and permit conditions 1.2 and 3.2 specifies	AIR	The EIS text has been revised to reflect the status of the IDEQ permitting and preparation of a dust control plan. USFS will prior concurrence with the plan. Additionally, dust control monitoring has been added as a mitigation measure within Section 4.3.5 of the Final EIS.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>93% dust control must be met for the haul roads. The FDCP was not provided in the PTC before it was issued and has not been available for public review. EPA recommends the FEIS include a draft of the FDCP as an appendix or publicly available reference document.</p> <p>The IDEQ PTC does not contain any requirements for PM monitoring as is stated above in the first paragraph. The EPA has recommended PM10 monitoring in previous cooperating agency NEPA comments and in comments to IDEQ during the draft air permit comment period.</p> <p>For the FEIS, EPA continues to recommend continuous PM10 monitoring at the facility fenceline, as a mitigation measure and integral part of the FDCP, to ensure the project will not cause a violation of the primary and secondary National Ambient Air Quality Standards. Monitoring is justified based on the high range of uncertainty in the estimates of fugitive dust emissions and high potential of potential impacts to resources in the project area.</p> <p>Though the DSEIS modeling indicates that PM10 impacts will be below the NAAQS, the modeling was based on numerous assumptions, including achieving a 93% control efficiency on fugitive dust emitted from haul roads. Small errors and uncertainties in the emission inventory assumptions could lead to significantly more fugitive dust emissions than estimated. In its prior comments to IDEQ, EPA raised concerns about the feasibility and enforceability of achieving the 93% control efficiency. PM10 monitoring would help to verify the estimated emissions in the assessments were correct or provide a measurement tool to gauge the effectiveness of post-project mitigation to address excessive emissions.</p>		
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	17	<p>Access Road</p> <p>The DSEIS states “[t]he EPA Region X has indicated that the access road could possibly be excluded from ambient air if sufficient measures are taken to comply with the 2019 revised policy (EPA 2019a).”EPA recommends disclosing that formal EPA policy review of the proposed ambient air boundary was not requested by the state and was not conducted. The EPA does not typically engage in formal review of the ambient air boundary during NEPA review and usually only conducts such a review upon request of the state during air permitting.</p> <p>For the FEIS, EPA suggests the following to add to the paragraph: “Exclusion of the public access road from ambient air protections is a unique case that relies on measures assumed to meet the standards inferred in the 2019 revised ambient air policy. However, a formal EPA policy review of the ambient air boundary for the project has not been conducted nor requested. A formal review is not necessarily required. The EPA did provide formal comment on IDEQ’s air quality PTC recommending a review be requested by the state and that initial measures in the PTC were too ambiguous to determine compliance with the revised ambient air policy.”</p>	AIR	The requested language regarding the EPA position on use of the public access road through the mine site has been included in the EIS.
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	18	<p>Arsenic Screening Analysis</p> <p>The EPA continues to have concern that the arsenic screening analysis underestimates cumulative impacts of airborne arsenic to the environment in the vicinity of the project. The results presented on page 4-46 of the DSEIS, and Table 4.3-13 are compared to an annual acceptable ambient concentration for a carcinogen (AACC), the Idaho toxics screening threshold. However, this screening threshold is not necessarily intended to be compared against a 70-year lifetime scenario where 57 years of the period assumes zero exposure. The threshold is an annual average used for screening, prescribed as a de-minimus value based on lifetime risk. Under IDEQ’s hazardous air pollutant program, in practice, project impacts from the maximum year of emissions would typically be compared to the annual average AACC for arsenic.</p> <p>If the impacts were determined using annual average emissions during the period of the project only, the resulting arsenic concentrations would exceed the AACC. There is significant uncertainty in the emission rates of fugitive dust associated with the project such that arsenic emissions could be underpredicted.</p> <p>Based on these concerns, the EPA continues to recommend the FEIS include an expanded cumulative analysis to disclose project airborne arsenic impacts to the environment.</p>	AIR	The AACC were derived from the EPA unit risk factor which is the relative risk of excess cancers from being continuously exposed to 1 microgram of the substance in one cubic meter of air for a period of 70 years and expressed in terms of a screening emission level or an acceptable ambient concentration for a carcinogenic toxic air pollutant. See IDAPA Section 005.125 definition of Toxic Air pollutant Carcinogenic Increments. Also, in communication with IDEQ, it has been determined that this calculation approach is deemed acceptable.

Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	19	Retort Emissions The DSEIS states “[t]he retort emissions are based on an average of two refinery reports in 2015/2016 (NDEP 2015, 2016). The corresponding calculations are 20 percent of the retort standard of 0.8 lb/ton.” The process by which these emissions are derived is unclear. The two referenced documents (NDEP 2015, 2016) contain emission values for over 25 mining operations in Nevada. Depending on the mine, the emissions can be less than 1 lb/year to greater than 500 lbs/year. For the FEIS, EPA recommends providing information on which two ref	AIR	The retort emissions are based on reported emissions from the autoclave facilities at the Twin Creeks Mine and the Goldstrike Mine as reported through the Nevada Division of Environmental Protection.
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	20	Gaseous Elemental Mercury (Hg0) Emissions The DSEIS indicates that gaseous elemental Hg0 emission sources at the SGP will be controlled by activated carbon absorbers. If Hg0 emissions are controlled by the activated carbon absorbers, EPA recommends the FEIS clarify if this means that the 13.6 lb/year of Hg released from the SGP project will consist of particulate bound and oxidized Hg. EPA further recommends clarifying for the AERMOD assessment, if all 13.6 lbs of Hg are included in this modeling.	AIR	The analysis included all mercury species. The sources included propane combustion, the autoclave system, refinery sources, process dust, mine fugitive dust and mercury flux. This is incorporated in the 13.6 lbs/yr. Depending on the activity, the speciation is either all Hg0, Hg2 or HgP. Appropriate clarification language has been added to the Final EIS where appropriate.
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	21	Underestimations of Total Hg Deposition The DSEIS states “[t]his analysis indicates a maximum estimated increase in Hg deposition rate of 0.4 percent or less of the existing background rate. However, it should be recognized that this rate underestimates the total Hg deposition, as the mechanism of Hg0 flux is not included in the screening model.” While we appreciate the inclusion of the sentence indicating a reason why this percent increase is underestimated; the reason listed is only part of the reason for the underestimation. As mentioned in a previous section, the background Hg deposition values based on data from more than 10 years ago is also biased high due to subsequent emission controls. Therefore, the 0.4% increase underestimates Hg deposition because 1) it does not include Hg0 deposition; and 2) the background deposition rates are overestimated for current conditions. Generally, when developing an EIS on the impacts of a proposed mine, the preference is to develop conservative estimates of potential impacts and provide caveats as to why these impacts may be overpredicted. For this SEIS there are several instances where impacts are underpredicted and then caveats are added indicating that there is a low bias in the analysis. The problem with this approach is that impacts may not be identified and properly mitigated. EPA suggests adjusting the Hg deposition assessment for the FEIS to conservatively estimate the potential impacts and then provide caveats as to why these impacts are likely overpredicted.	AIR	The estimates for total Hg deposition are based on the information available at the time of developing the SDEIS. The analysis discloses uncertainties in its forecasting and the use of potentially non-conservative assumptions to provide context for its forecasts and estimates. The background deposition rates for the area have not been remodeled or re-estimated to assess the effects of emission controls on deposition.
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	22	Contribution Above Estimated Hg Background Table 4.3-18 SGP Contribution Above Estimated Hg Background indicates that SGP will result in Hg deposition of 0.056 g/km2/year. However, an earlier Table (4.3-6) indicates that the mine will release 13.6 lbs per year of Hg. The previous statement that Hg0 emissions will be controlled suggests that 13.6 lbs represents releases of oxidized and particulate bound fractions which will be deposited relatively locally. Of the 6,200 grams of Hg released (which is mostly or entirely Hg2+ and HgP according to the previous statement in the SEIS), AERMOD predicts only 0.056 g/year is deposited with a square km. There seems to be a disconnect between the species of Hg emitted, the amount of Hg emitted, and the amount being deposited locally within this analysis. EPA recommends reevaluating these analyses, making appropriate corrections for the FEIS, and if potential significant deposition is identified, mitigating to reduce impacts.	AIR	The EIS has been revised to clarify the characterization of the Hg emissions including its mass, speciation, and local deposition.
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	71	Air Quality • The SDEIS indicates deposition of mercury, and nitrogen and sulfur species were predicted to be less than Significant Impact Levels (SILs). EPA notes that SILs are air quality screening thresholds not	AIR	SIL terminology has been updated in the Final EIS. The recommended SIL language has been added to the Final EIS. Far-field language has been added. CFR reference updated. All other recommended editorial changes have been made. Also, Table 3.3-11 numerical errors have

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>applicable to deposition of pollutants, so this statement is incorrect. For the FEIS, EPA recommends replacing this term with “applicable screening thresholds,” or another appropriate term.</p> <ul style="list-style-type: none"> • The DSEIS states “SILs are defined concentrations of criteria pollutants in the ambient air that are considered inconsequential in comparison to the NAAQS. A project impact shown to be below a SIL can be presumed to not cause or contribute to the violation of a NAAQS.” <p>The first sentence in this paragraph is misleading. For the FEIS, EPA suggests the following language replace the first sentence: “SILs are screening thresholds of criteria air pollutant concentrations considered by the EPA as a level of de minimis impact to air quality. SILs are primarily used in air quality modeling assessments, where a project impact shown to be below a SIL can be presumed to not cause or contribute to the violation of a NAAQS.”</p> <ul style="list-style-type: none"> • EPA recommends the FEIS clarify or note in Section 3.3.2 why the much larger “far-field” region’s scope is of importance to the Tribes, given the potential impacts of poor ambient air quality to wilderness areas of Tribal and cultural significance. • The DSEIS states “[t]he New Source Review process requires facilities to undergo an EPA pre-construction review if they propose building new facilities or modifying existing facilities that would result in a “significant increase” of criteria pollutants per 40 CFR § 52.2376.” For the FEIS, EPA recommends changing the regulatory cite from “52.2376” to “52.21” and “criteria pollutants” to “regulated NSR pollutants.” • The DSEIS states “[a]pplicability of the PSD program to the SGP depends on the magnitude of annual emissions for criteria pollutants.” We recommend the FEIS revise this sentence to be more precise: “Applicability of the PSD program to the SGP depends on the project’s potential to emit regulated NSR pollutants. Applicability is determined using maximum potential annual potential emissions of the project for each NSR pollutant.” • The DSEIS states “... the 2021 MMP analysis did include an assessment of the significance of SGP air quality impacts by comparison to the Class II PSD increments.” EPA suggests the FEIS add an additional sentence to disclose why the PSD increment is selected as a threshold to assess the significance of air quality impacts. For example, additional language could state: “The PSD increments may provide a reasonable significance threshold for NEPA assessment because, under the Clean Air Act, significant air quality deterioration is recognized to occur when the amount of new air pollution from a new or modified source would exceed the applicable PSD increment.” • The DSEIS includes a statement “...consistent with best available control technology for new surface mining and processing operations” which is incorrect. The project did not go through BACT review under the IDEQ PTC process because it did not go through major-source PSD permitting. EPA recommends removing the reference to BACT in the FEIS. A similar statement is included at the top of page 4-59 which EPA recommends revising to remove the reference to BACT. • EPA suggests the FEIS revise the second sentence on page 4-38 to read “As shown in Table 4.3-4, IDEQ determined that these emissions are less than the annual threshold of 100 tpy that would trigger Title V or 250 tpy for PSD permitting status.” • Regarding DSEIS statement on page 4-43 “...it also is unlikely the SGP would cause or contribute to a violation of a PSD increment” and Table 4.3-9 column heading “PSD Increment Compliance”, it is important to disclose that comparison to the PSD increment threshold in the EIS is not to determine compliance to the standard (this is not a full regulatory assessment of increment consumption) but as a measure of the significance of project impacts to air quality for purposes of NEPA review. Therefore, we recommend the FEIS add a sentence to state the results instead indicate the project does not cause a significant deterioration of air quality. Also, EPA suggests changing the column header for Table 4.3-9 from “PSD increment compliance” to more appropriate wording such as “Results below threshold” or something similar to show the comparison is used to judge significance of project impacts rather than compliance with a regulatory threshold. 		<p>been remedied. A PSD classification discussion has been added to the Final EIS in Section 3.3.3.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<ul style="list-style-type: none"> • For the DSEIS statement “[t]he most recent measurements were between 2007 and 2010 and are provided in Table 3.3-10 to serve as an estimate of historical Hg deposition in the region surrounding the SGP area,”⁸⁰ EPA recommends the FEIS add the word “wet” before deposition to specify that these data do not include dry deposition. • For Table 3.3-10 Historical Annual Average Concentration and Mercury Deposition Rates – Three Idaho MDN Sites, EPA recommends the FEIS add “in precipitation” to this Table title. • The DSEIS indicates the nearest geographic site to the SGP area is no longer active but was active from December 2008 to August 14, 2017. For the FEIS, EPA recommends specifying that the nearest site is over 500 km away. • EPA notes that the Table (3.3-11) Annual Average Mercury Concentration – Salt Lake City AMNet Site contains an important error. The Table reports that the overall mean gaseous elemental mercury (GEM) concentrations is 12.91 ng/m³. This value is not accurate. All yearly averages shown above in the Table are less than 2.5 ng/m³; and if taking an overall mean of the annual means the value would be 1.88 ng/m³ which is much lower than the 12.91 ng/m³ value currently included in the Table. It appears that the values for particle bound mercury (PBM)_{2.5} and GEM were switched, because the PBM_{2.5} value listed is lower than all of the annual reported concentrations. EPA recommends the FEIS correct the error accordingly. • Regarding the DSEIS statement “[e]stimates of these emissions were based on regulatory compliance emission test results available for several gold mines in Nevada that use the same type of extraction process (Nevada Division of Environmental Protection 2006, 2015, 2016),” for the FEIS, EPA recommends the FEIS add whether the mercury content of the ore was significantly different in the comparison between Stibnite and the Nevada mines. • The DSEIS states “[f]urther speciation of the particulate forms of Hg is possible such as fine [particle-borne Hg (HgP)], which is analogous to filterable and condensable PM₁₀. Essentially, the PM₁₀ associated with HgP is the mercury bound within the particles of the particulate smaller than 10 microns. Appropriate particle distribution of mercury can be established using proper test methods and techniques, but the overall percentage of HgP compared to total Hg is small, with HgP PM₁₀ being even less (~14.1 percent vs 2.4 percent from a coal boiler as an example) (Peng 2021). However, as discussed below, and in further detail in Section 4.3.4.2, the approach applied for this analysis did not speciate HgP.” EPA notes that this statement appears superfluous, given that particulate bound Hg was not further speciated in the analysis. EPA suggests the FEIS include some context for why this information is included or consider removing it. 		
Small, Nathan (Chairman, Fort Hall Business Council, Shoshone-Bannock Tribes)	18903	16	The SEIS indicates a claim that the Project can contain over 90% of all emissions from operations, and that there are metrics for controlling those emissions from the operations over the life of the mine. While this may be factual, there will not be any requirement to actually engage in monitoring for air quality so there won't be any data to confirm these statements. At a minimum, the Tribes request that monitoring for Air Quality be required for all components of the Project as a condition of this permit and that those results be measured against established parameters for air quality; with the requisite fines associated with violations during operations.	AIR	Dust monitoring has been added to the Final EIS as mitigation. Please refer to Section 4.3.5 of the Final EIS and Section 7.3 of the Air Quality Specialist Report.
Small, Nathan (Chairman, Fort Hall Business Council, Shoshone-Bannock Tribes)	18903	35	The lime kiln should be permitted by the Idaho DEQ.	AIR	The current IDEQ PTC does permit the lime kiln (known as the parallel flow regenerative kiln in PTC). The throughput limit is PC 5.5. PC5.12 is the development of the baghouse O&M manual. PC 5.18 are the monitoring requirements. 5.23 is the baghouse monitoring requirements.
Small, Nathan (Chairman, Fort Hall Business Council,	18903	36	Mercury emissions of any kind or amount are unacceptable. Please eliminate the retort step or whatever is necessary to eliminate all mercury emissions.	AIR	Mercury emissions would be mitigated as much as possible. There would be a non-zero amount, but the retort is subject to NESHAPS 40 CFR Part 63, Subpart 7E, which requires the

Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19235	141	The HCN (tpy) process (r 2, c 2) and fugitive (r 3, c 2) emissions are switched.	AIR	Edit has been made - confirmed with 2018 Emissions Inventory.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19235	142	"The results illustrate that the overall impact from the associated HAPs would be moderate, but well below the IDEQ permitting thresholds." This should be described as "minor" because the AACC are screening level thresholds. Modeling is conducted at the project boundary, not for sensitive receptors - and no risk analysis is required for impacts less than the AACC. Also, IDEQ allows impacts to be 10 times higher if you install T-RACT controls. SGP is installing T-RACT controls and demonstrates compliance with AACC without taking the 10x credit, i.e., impacts are minor.	AIR	Context language added along with recommended edit to less than significant.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19235	143	The ug/m3 values in r 3, c 3, 4, 5 are incorrect. Correct values are 3.0, 118, and 120 at 25C and 1 atm.	AIR	The original comment references Table 7.13 of AQ SR. The first row values in that table are taken from ASI 2021a; Table 8. There is no third row, but the second row does have an error. Based on a conversion of ppb x 1.96 = ug/m3 (based on a MW of 48 g/mol and a conversion factor of 24.45), the row has been updated. The values are 2.7, 117.8, and 120.5.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19235	144	Please correct to "east" to "west" in r 2, c 1.	AIR	Edit has been made - confirmed with ASI 2018a, ASI 2021a.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19235	145	Please correct reference "Air Sciences 2018b" to "Air Sciences 2018a."	AIR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19235	146	Please correct reference "Air Resources 2018b" to "Air Sciences 2018a."	AIR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19235	147	Please correct reference "Air Sciences 2018b" to "Air Sciences 2018a."	AIR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19235	148	"Using the same stringent Class I criteria for the Class II wilderness areas included in this analysis demonstrates that the level of regional haze impact in these areas is predicted to be minor. " This should be described a "negligible." Per the FLAG (2010) document: "After CALPUFF is run, CALPOST is used to evaluate whether the proposed source or modification will be below the Agencies' threshold for concern (i.e., 5% change in light extinction)." Therefore, impacts below the "threshold of concerned" should be considered "negligible."	AIR	Edit has been made to less than significant. This is appropriate as the results are well below extinction threshold.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19235	179	Please change "IV" to "Tier 2 certified or better" in b 18.	AIR	Change made as the 2021a Emissions Inventory does apply Tier 2 emission factors for the emergency units. Note that the fire pump emission factors are derived from 40 CFR Part 60, Subpart IIII Table 4. All engines must meet IIII, See PC 2.22 of the final IDEQ PTC.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19235	626	"Transport from far more distant urban regions, even overseas, may contribute to local air conditions (eTransport from far more distant urban regions, even overseas, may contribute to local air conditions (e.g., ozone) but are not in the scope of a cumulative effects analysis. " - This is incorrect. The impacts from distance sources should be disclosed in the No Action. If it truly is affecting local air quality, it needs to be disclosed in the cumulative effect, although it might not be able to be quantified. They certainly are within the scope of the analysis. Maybe this meant to say they are not quantified.	AIR	Text update made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19235	627	"The ambient air data for CO, NO2, SO2, and on-site data for PM10 and PM2.5 indicate the existing impacts from off-site sources on air quality near the SGP area was reviewed for this analysis (Section 3.3). These background ambient air measurements offer the best indication of cumulative effects due to current emissions sources. Although some background measurements of ozone in the Boise urban area are above the NAAQS, the ozone baseline value for this assessment recommended by the IDEQ is compliant with the NAAQS. The monitored baseline values used for the SGP air quality impact assessment were obtained at locations that are more developed than the SGP area. By comparison, the cumulative effects in the analysis area due to current activities and air emission sources would be minor. " Recommend these sentences be moved to the No Action section.	AIR	Moved to Section 5.3.1 (No Action).
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19235	628	"There are no other permitted sources of HAP emissions in the vicinity of the SGP area. One source, the Tamarack Mill, LLC is 75 miles from the SGP, and has reported minor source level emissions to IDEQ. The HAP emission inventory in the vicinity of the SGP area is unknown; however, given the absence of large HAP emission sources near the SGP area, it can be assumed that the baseline HAP cumulative effects are low. " Recommend these sentences be moved to the No Action section.	AIR	Moved to Section 5.3.1 (No Action).
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19235	629	"RFFAs Considered Regarding Cumulative Air Quality Effects for Specific Planning Projects " Please provide information about whether these projects will be concurrent with SGP.	AIR	Expected timing for planning projects are described in Table 5.1-2. Although subject to scheduling changes, these projects are currently expedited to be concurrent with the Project.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19235	630	"Natural Emission Events: Wildland fires " This is not an action. Please delete.	AIR	Revision not made. Inclusion of wildfires as an RFFA is appropriate.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19235	6	Technical reviewers of Sections 3.3, 4.3 and the Air Quality Specialist Report indicate that the SDEIS accurately reflects the updates and revisions provided to the United States Forest Service (USFS) in previous reviews. Perpetua Resources appreciates the USFS' attention and consideration of comments on prior versions of the report, and general observations are that applicable sections of the SDEIS, and the Air Quality Specialist Report in particular, represent an accurate description of work completed to assess the air quality impacts. Attachment A includes minor technical comments to ensure accuracy of the information included in the SDEIS.	AIR	Comment Noted. No further response required.
John Robison	19330	5	Close the site, I am also concerned about air quality, particularly arsenic levels in the dust. The Forest Service should require additional design features to control dust and have real time monitoring of arsenic	AIR	Additionally, the PTC IDEQ permit requires low-arsenic quartzite (90 ppm or less) for haul road capping. The Final EIS includes a dust monitoring requirement.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			levels around the Operations Area Boundary and along the public road through the mine site to Thunder Mountain.		
John Robison	19330	10	On the eastern end of the project area, I am concerned about how mining activities will affect my wilderness experiences in the Frank Church River of No Return Wilderness on the Middle Fork of the Salmon River. Sunset is one of my favorite times and I am worried that a plume of pollution will mar the skyline or drift over my camp. I also seek out Dark Sky experiences and I am concerned that the lights from mining activities will degrade this experience. The Forest Service needs to develop additional design features to address these visual impacts.	AIR	<p>The associated air quality pollution associated with the Project has demonstrated that the expected emissions meet all national ambient air quality standards, which are protective of human health. The visibility potential has been analyzed using EPA modeling approved methods. The VISCREEN analysis indicates that at the maximum potential operating rate, the SGP emissions plume might be visible for 0.02% of annual daylight hours, under certain viewing conditions. The VISCREEN analysis was performed separately for each hour of the 2014 onsite meteorological data with winds that could potentially intersect with the FCRNRW boundary, a Class II area near the facility. The VISCREEN results were evaluated on an hourly basis. It further indicates that a plume would not be visible most days, and under certain viewing conditions for which the plume would be seen should only last for approximately one hour. The number of daytime and nighttime visible plume hours for each of the eight viewing conditions evaluated in VISCREEN are tabulated in (Air Sciences 2021a), Appendix C.</p> <p>The SGP VISCREEN analysis accounted for the seasonal variation in daytime and nighttime hours; i.e., there is no assumption of 12 hours of daytime and 12 hours of nighttime hours per day. Instead, the daytime or nighttime determination was performed for each hour by comparing to the day-specific sunrise and sunset times. The site-specific sunrise and sunset times were calculated based on the longitude and latitude of the onsite meteorological tower using the EPA regulatory methods found in the MPRM meteorological data processing program.</p>
Jesse Lutz	19386	7	<p>On a clear day one can easily observe a smoke plume on the Nez Perce National Forest clear across the Salmon River from the heights of Sugar Mountain (just above the proposed site of operations and in the Wilderness). That is approximately 40 air miles.</p> <p>What would be the outcome if there were an inversion or wind event?</p> <p>How often and for how long would they occur?</p> <p>Where will the plume settle and How far from the site?</p> <p>Will it settle into the private property of the Monumental drainage (within the Wilderness and Analysis area)? Will it settle in the nearby Edwardsburg Community (Surrounded by the Wilderness and within the Analysis area) and how many acres would it encumber?</p> <p>Will it settle in Yellowpine community (withing the Analysis area) and are the potentials to create thick fog layered with particulates from operations?</p> <p>Will it settle in the mine operations area affecting workers health while outdoors (dead center of the Analysis area)?</p> <p>There are unknowns that are still not addressed in the DEIS. It seems drafted to show 'ideal conditions'. What is the baseline for this information at elevation and location within atmospheric sink zones? Can those be designated to show the general public areas to avoid during weather conditions which could create them?</p> <p>Could you address these outcomes with more specific data and the manner with which it is collected?</p> <p>It will settle on National Forest System lands. How will the users recreating on the forest be influenced by the decrease in air quality produced by the proposed project? Relocation is not a preferred alternative, not only because of air quality or because of the 'visual' influences on developed characteristics from the proposed mining activities but also because of the increase in traffic, on all routes. Opportunities for recreation on National Forest Systems lands and WOTUS is equal to everyone.</p>	AIR	<p>The air quality pollution associated with the Project has shown that the expected emissions meet all national ambient air quality standards, which are protective of human health. The visibility potential has been analyzed using EPA modeling approved methods. The VISCREEN analysis indicates that at the maximum potential operating rate, the SGP emissions plume might be visible for 0.02% of annual daylight hours, under certain viewing conditions. Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	161	2. Airborne arsenic carcinogenic risks are underestimated 192 Table SD10 in the SDEIS summarizes the appropriate correction factors for Haul Road emissions and includes combination factors for As concentration, silt content, and % Particulate Control adjustments. Applying any combination of adjustments >1.5 would result in excess cancer risk. Correcting for silt content, percent control, and pit-specific concentrations for all pits likely increases to concentrations >10-5 cancer risk levels.	AIR	Section 4.3.2.2 compares arsenic dust concentrations to HAP standards. Attainment of standards precludes developing a separate human health risk analysis.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	347	We have repeatedly raised concerns throughout the permitting of the SGP at both federal and state levels regarding the SGP's significant potential air quality impacts. The Idaho Conservation League, Save the South Fork Salmon, and the Nez Perce Tribe are currently engaged in an administrative appeal of the IDEQ PTC (IDEQ Case Docket No. 0101-22-02383). That state air process is important but does not replace the Forest Service's obligation to analyze and mitigate impacts to air quality in the NEPA process. We note that the Forest Service's mandate under NEPA when evaluating impacts to air quality is much broader than IDEQ's mandate in the PTC process under the Idaho Air Quality Rules. Importantly, the Forest Service retains the authority to require certain conditions for the SGP that help minimize and/or mitigate the project's impacts to air quality. Thus, even if IDEQ did not or could not add certain conditions in their PTC for this project, the Forest Service can (and should) include appropriate conditions as part of the FEIS and ROD for the SGP in order to fulfill the agency's obligations under NEPA.	AIR	Noted. Multiple mitigation measures have been added to the Final EIS, see Section 4.3.5 and 7.3 of the Air Quality Specialist Report.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	348	In order to ensure the SGP does not violate the NAAQS for PM and PM10, the Forest Service should require Perpetua to install an arsenic and PM/PM10 monitoring system at the SGP's ambient air boundary to ensure that the arsenic AACC and the PM/PM10 NAAQS are not violated. This kind of monitoring is not a condition of the current PTC issued by IDEQ for the SGP, and therefore is unlikely to happen unless the Forest Service requires it. This practical step is warranted considering the uncertainty surrounding dust control efficiency and emissions factors associated with this project and highlighted in the below comments.	AIR	As part of the Final EIS, a dust monitoring program has been added as a mitigation measure, see Section 4.3.5.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	349	a. Title V Applicability Section 3.3.3, page 3-35 of the SDEIS states, "a determination was made by the IDEQ that the SGP would not require a Title V permit. This was based on the complete air emissions inventory for stationary sources submitted by Perpetua as part of its application for an air quality permit. On February 18, 2022, Perpetua submitted a PTC application and emission inventory. On June 17, 2022, IDEQ issued a final PTC and Statement of Basis (SOB) stating that the SGP will not require a Title V permit." However, this is demonstrably false. Page 32 for the June 17, 2022, SOB states, "Any source subject to 40 CFR 63, Subpart EEEEEEE is a Tier I source as defined in IDAPA 58.01.01.006.122.c" (in the state of Idaho, Title V sources are known as Tier I sources). The gold ore concentration and refining process equipment associated with the SGP is specifically applicable to 40 CFR 63, Subpart EEEEEEE. Accordingly, PTC permit condition 2.23 and 2.24 specifically requires Perpetua to submit a Tier I application to IDEQ within 12 months of start-up of the gold ore concentration and refining process equipment. Based on recent discussions with IDEQ, the agency has not yet determined whether the future Tier I permit will cover only the Tier I applicable equipment (gold ore concentration and refining process equipment) or all equipment/sources covered by the final PTC will be discussed as a matter of IDEQ discretion upon Perpetua's submittal of the Tier I application. The Forest Service should correct the statement on page 3-35 of the SDEIS regarding Title V applicability	AIR	The SDEIS had an error. The requirement of a Title V permit has been incorporated into the Final EIS.
Bonnie Gestring (Northwest Program Director,	17634	350	3. Dust Control Efficiency Both the Forest Service's and IDEQ's fugitive dust analyses in the SDEIS and PTC, respectively, heavily rely on the assumption that Perpetua can achieve a dust control efficiency of at least 93.3% on the SGP haul roads in order to minimize PM10 emissions and achieve NAAQS compliance. However,	AIR	Perpetua provided a technical memorandum to the USFS on March 18, 2021 outlining the rationale for the 93.3% control through use of suppressants. This document discussed several studies whereby the PM10 control of 93.3% plus was attainable. Regardless, of that the Final EIS will agree with the IDEQ PTC that requires records of applicable use of suppressant every 12 hours (PC 2.2) and they must abide by the approved FDCCP. Additionally, dust

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Earthworks) and seven others			<p>neither the Forest Service nor IDEQ have provided sufficient evidence that such a high target is attainable or practically enforceable. In Appendix G of the Final IDEQ PTC Statement of Basis, IDEQ discusses the T-RACT Analysis, including dust control efficiency. We reviewed the references listed in Appendix G, Table 10 of other facilities with determinations of 90% or greater control efficiency for unpaved roads. Upon investigation of these references through the EPA's Clean Air Technology Center database, 387 ICL found that only 1 of the 10 facilities referenced actually has verified compliance of achieving at least 90% control efficiency. The other nine facilities listed in Table 10 had either unverified or unknown compliance with that permit condition. In addition, only one of these facilities is actually a gold mining operation and therefore most of these references should not be used as a point of comparison to the SGP.</p> <p>Listed Facilities in Appendix G, Table 10 AK Donlin Gold Project AK-0084 water/chem 90% unverified/unknown compliance)</p> <p>AR Turk Power Plant AR-0094 water/chem 90% (unverified/unknown compliance) CO Rio Grande Portland Cement Corp. CO-0043 water/chem 90% (unverified/unknown compliance) IN Nucor Steel IN-0034 chem 90% (unverified/unknown compliance) LA Nucor Steel Louisiana LA-0239 water/chem 90% (unverified/unknown compliance) MO Lafarge Corp. MO-0048 chem 90% (unverified/unknown compliance) NV Sloan Quarry NV-0045 chem 98% (compliance verified, but not a gold mine) NV Nellis Air Force Base NV-0047 water/chem 90% (unverified/unknown compliance) OH Unlimited Concrete OH-0126 water/chem 90% (unverified/unknown compliance) OH Unlimited Concrete OH-0131 water/chem 90% (unverified/unknown compliance)</p> <p>The 93.3% level of control which the Forest Service and IDEQ assumed Perpetua could achieve is based on Perpetua's interpretation of EPA's AP-42 Chapter 13.2.22. AP-42 Chapter 13.2.2 discusses the critically important variables surrounding control efficiencies (in particular to chemical suppressants, some of which can reasonably be assumed to apply to water too):</p> <p>"The control effectiveness of chemical dust suppressants appears to depend on (a) the dilution rate used in the mixture; (b) the application rate (volume of solution per unit road surface area); (c) the time between applications; (d) the size, speed and amount of traffic during the period between applications; and (e) meteorological conditions (rainfall, freeze/thaw cycles, etc.) during the period. Other factors that affect the performance of dust suppressants include other traffic characteristics (e.g., cornering, track-on from unpaved areas) and road characteristics (e.g., bearing strength, grade). The variabilities in the above factors and differences between individual dust control products make the control efficiencies of chemical dust suppressants difficult to estimate. Past field testing of emissions from controlled unpaved roads has shown that chemical dust suppressants provide a PM-10 control efficiency of about 80 percent when applied at regular intervals of 2 weeks to 1 month (emphasis added)."</p> <p>None of the above variables, however, have any specific and enforceable permit conditions within the PTC to ensure a 93.3% control efficiency. Instead, the PTC has a permit condition (permit condition 2.6) only requiring the permittee to develop and submit a Fugitive Control Dust Plan (FCDP) and a Haul Road Capping Plan (HRCP), which merely describe how these variables will be addressed 30 days before start-up of the SGP. PTC permit condition 2.6 details what variables contributing to PM10 control effectiveness must be detailed in the FCDP, but the specific details that are so important to control efficiency (e.g., the amount of water or chemical suppressants applied and the frequency of application) are undetermined at present and are left to Perpetua to decide at a later date. A lesser control efficiency, even just slightly lesser, could result in large enough PM10 emissions to violate the NAAQS. In fact, if the SGP were to instead achieve 80% control (as EPA found through past field testing of chemical dust suppressants), then the SGP's PM10 emissions could exceed the NAAQS.</p>		<p>monitoring will be part of the mitigation measures in the Final EIS (Section 4.3.5) and the Forest Service has adopted the 93.3% efficiency for assessment of emissions. The FDCP would be developed and approved prior to commencement of construction.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>Furthermore, IDEQ itself states on page 22 of the final SOB that “it may prove challenging to consistently and continuously achieve the targeted level of fugitive dust control for emissions from traffic on unpaved roadways, with over 55 miles of haul truck routes within the mining operations boundary, a fleet of 32 haul trucks weighing between 37 and 357 tons, and a targeted dust control efficiency of 93.3% accomplished by application of both dust suppressant and water controls.”</p> <p>The Forest Service should include specific provisions in a revised SDEIS designed to verify whether key dust control efficiency metrics are met during SGP construction, operation, and closure.</p>		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	351	<p>4. Haul Road Emissions Calculations</p> <p>In the process of calculating fugitive dust emissions from ore road hauling, Perpetua has again relied on the EPA’s AP-42 Chapter 13.2.2. Equation 1a of AP-42 Chapter 13.2.2 provides an equation that Perpetua used to calculate a particulate matter size-specific emission factor (in pounds per vehicle mile traveled) that is in turn used to calculate total PM2.5 and PM10 emissions that were evaluated in both the SDEIS and IDEQ PTC process. Equation 1a uses three empirical constants (with values provided by AP-42 Chapter 13.2.2) and two variables. These two variables are the silt content of the road traveled and the mean weight of the vehicles traveling the road. IDEQ final PTC permit condition 3.13 requires the SGP to use haul road capping material with a maximum silt content of 4%, thereby constraining the first of the two key variables used in Equation 1a. However, no such permit condition exists in the PTC or the SDEIS to constrain the second variable, mean vehicle weight. In calculating fugitive haul road emissions evaluated in both the SDEIS and IDEQ PTC process, Perpetua assumed an operating scenario using twenty larger CAT 789D and twelve smaller CAT 740D trucks for all ore hauling (see final SOB, Appendix A, Page 5 of 20 Mine sheet) each with a listed hauling capacity and empty weight that are used as inputs to equation 1a. However, if the ratio of larger to smaller CAT trucks is shifted in favor of additional smaller CAT 740D trucks, then calculations will show the particulate matter size-specific emission factor can dramatically increase thereby increasing overall PM2.5 and PM10 emissions.</p> <p>Instead of developing PTC conditions for this critical variable, IDEQ relied on a surrogate limit in the IDEQ PTC (total ore haulage per day, see PTC conditions 3.5) and on plans that have not yet been developed—the FDCP and the HRCP—to claim the PTC ensures enforceable compliance with 24-hour PM10 NAAQS. Without including an IDEQ PTC condition or a FEIS requirement that specifically constrains mean vehicle weight, the SGP may use a combination and number of ore hauling trucks that drastically increases PM2.5 and PM10 emissions, threaten compliance with the NAAQS and underestimate the environmental impacts within the SDEIS analysis.</p> <p>The Forest Service should include requirements within a revised SDEIS stipulating the number and weight of ore haul trucks that may be used in SGP operations such that ore hauling emissions are consistent with the SDEIS assumptions and calculated emissions.</p>	AIR	The emission estimates for the SDEIS/Final EIS are based on the use of the CAT 785D and CAT745C. The current haul truck is based on the weight average of 180 tons (CAT 785D and CAT 745C) based on expected annual operating hours per year for each type of trucks (similar to the PTC weight of 182.6). The calculated total of emissions is based on approximately 5.55x more hours with the CAT785D. If that ratio is increased emissions increase incrementally; conversely, the lower it becomes the lower the emissions. Current PM2.5 emissions are calculated at 20.13 tpy. If 15,000 hrs were added to the 785D (decreased from the 745C), emissions would be ~21.04 tpy. If 15,000 are removed from the 785D and added to the 745C, emissions reduce to 19.17 tpy. Similarly, with an increased weighted average tonnage, the emissions are increased. The Forest Service decision on the proposed mining project includes the proposed mine rate and its associated mobile equipment emissions. An increased mining rate above the proposed tonnages would require additional permitting.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	352	<p>5. Operational Plans</p> <p>As noted in previous comments, operational plans like the FDCP, HRCP, and the Operation and Maintenance manual (O&M) are a particular point of concern. IDEQ has required Perpetua to complete these plans as a condition of the IDEQ PTC for which the SDEIS bases its air quality impacts analysis on. However, despite the FDCP, HRCP and O&M clearly being central to the SGP’s mitigation of air quality impacts, the public will not have the opportunity to review and comment on these plans. Without developing the FDCP, HRCP and O&M before start up of the SGP, and without including all important variables as enforceable IDEQ PTC permit conditions or FEIS requirements, there is no assurance the SGP will comply with the PM10 NAAQS, avoid additional environmental degradation and will not pose a risk to public health.</p> <p>Given that the specifics of the FDCP, HRCP, and O&M are essential to ascertaining exactly how the applicant will achieve the lofty 93.3% dust control efficiency, the SGP should not be allowed to commence construction until a FDCP, HRCP and O&M are submitted to the Forest Service and IDEQ, reviewed by both the Forest Service, IDEQ, and the public, and approved or denied pending modifications. While the IDEQ PTC currently requires Perpetua to submit the FDCP, HRCP, and O&M</p>	AIR	The FDCP and other operating plans such as the Haul Road Control Plan and O&M Manual would be reviewed by USFS with concurrence prior to commencement of construction.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>for agency review 30 days prior to commencement of operations at the SGP, that process contains no public review process and essentially circumvents the public review process for which the rest of the PTC and its analysis are required to go through. Furthermore, holding agency review of these plans merely 30 days before commencement of operations could be considered little more than an afterthought process. Nearly all other operational aspects of SGP project operations will be finalized at that point, likely allowing for little modification should Perpetua’s proposed FDCP, HRCP, and O&M prove inadequate.</p> <p>The Forest Service should include requirements within a revised SDEIS stating a FDCP, HRCP, O&M must be submitted for Forest Service review and public comment prior to issuance of the FEIS.</p>		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	353	<p>6. Modeled Arsenic Emission Rate</p> <p>Section 7.2.2.2 of SDEIS Air Specialist Report discusses the analysis of the modeled arsenic emission rate. Since there are no NAAQS-like equivalent concentrations for Hazardous Air Pollutants (HAPs), the SDEIS analysis of arsenic relies on IDEQ state regulations governing arsenic and their comparison to Idaho state ambient annual carcinogen concentrations (AACC). Due to different operating scenarios used to calculate emissions, modeled SGP arsenic emission concentrations between the IDEQ PTC process and SDEIS differ. However, both analyses average out their respective calculated arsenic emission concentrations over 70 years citing the fact that the annual averaging period AACCs provided in the Idaho rules (IDAPA 58.01.01.586388) were developed “based on the probability of developing excess cancers over a seventy (70) year lifetime exposure to one (1) microgram per cubic meter (1 ug/m3) of a given carcinogen and expressed in terms of a screening emission level or an acceptable ambient concentration for a carcinogenic toxic air pollutant.” However, nothing in the Idaho Air Rules allows for ambient air concentration averaging over 70 years. Rather, the Idaho AACCs are deliberately set as annual averages. IDAPA 58.01.01.586 specifically states, “the screening emissions levels (EL) and acceptable ambient concentrations (AACC) for carcinogens are as provided in the following table. The AACC in this section are annual averages” (emphasis added). The AACC are not noted as being “lifetime” or 70-year averages. Furthermore, the Idaho rules addressed the question of short term sources in a specific but limited nature allowing sources who will operate for no more than five years to increase applicable AACCs by 10 fold (IDAPA 58.01.01.210.15).</p> <p>The probability within the “based on the probability of developing excess cancers over a seventy year lifetime exposure.” definition referenced above is defined by IDEQ as a 1 in 1,000,000 chance of developing cancer (see IDAPA 58.01.01.201.12.d). However, by averaging the SGP’s lifetime arsenic emissions concentration over 70 years, IDEQ is allowing Perpetua to essentially elevate and condense the normally allowable arsenic emissions over 70 years in just 14 years (LOM 3 to 16). In this way, higher pollution exposure is traded for less exposure time. Yet, there is no evidence within Idaho air rules that states or suggests the biological mechanism of carcinogenic exposure translates in a similar way. The development of cancer from carcinogens is linked to several critical variables including concentration, duration, frequency, and at your age at time of exposure³⁸⁹. IDEQ is assuming the variables of concentration and duration are linearly related when they have presented no such proof this is the case. It is possible higher levels of arsenic exposure, although in shorter duration, have a greater impact on cancer development risk than lower level exposure for a proportionally longer duration. If the goal of the AACCs is to prevent the probability of developing cancer in excess of 1 in 1,000,000, there is no evidence to suggest IDEQ’s approach is valid in achieving this goal.</p> <p>The Idaho Conservation League, Save the South Fork Salmon, and the Nez Perce Tribe contend that this action is an abuse of IDEQ regulatory discretion and are currently engaged in an administrative appeal of the IDEQ PTC specifically challenging this issue (IDEQ Case Docket No. 0101-22-02390). To our knowledge, there is no IDEQ air permitting project or source for which IDEQ has applied the same ambient air concentration averaging over 70 years. The Forest Service should not rely on IDEQ’s flawed analysis in evaluating the impact of arsenic emissions from the SGP.</p> <p>The Forest Service should re-evaluate arsenic concentration against Idaho AACC removing the 70-year lifetime averaging.</p>	AIR	As discussed in the SDEIS and the PTC SOB, the AACCs are derived from a 70-year exposure. IDAPA 58.01.01.005.125 states “Those ambient air quality increments based on the probability of developing excess cancers over a seventy (70) year lifetime exposure to one (1) microgram per cubic meter (1 µg/m3 of a given carcinogen and expressed in terms of a screening emission level or an acceptable ambient concentration for a carcinogenic toxic air pollutant.” This is consistent with IDEQ’s stance and because the SDEIS modeling utilized IDEQ standards for comparison purposes, use of the 70-yr exposure is appropriate.

Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	354	<p>7. Ambient Air Boundary Determination</p> <p>We are concerned that the exclusion of the public access road between Stibnite Road at Sugar Creek and Thunder Mountain Road at Meadow Creek from the regulatory definition of ambient air is inconsistent with Clean Air Act’s definition of ambient air, EPA’s long-standing policy that allows excluding certain areas of a source’s property from ambient air, and EPA’s most recent revised policy for ambient air (Revised Policy). Allowing the public to access this road, even under the conditions of the Stibnite Transportation Management Plan (SDEIS Air Quality Specialist Report, Appendix D), may result in acute exposure of the public to hazardous air conditions.</p> <p>EPA’s long-standing policy has been to exempt “the atmosphere over land owned or controlled by the source and to which public access is precluded by a fence or other physical barriers” from ambient air requirements. In 2019 EPA’s Revised Policy, recognizing advances in surveillance and monitoring capabilities, revised the “fence or other physical barriers element of this ambient air policy while maintaining public health protection” to allow stationary sources to use “other types of measures “to support exclusion of an area from ambient air.”</p> <p>It is important to note the Revised Policy specifically limited its scope stating, “... the sole change to the EPA’s ambient air policy reflected in this attachment is that the EPA no longer considers ‘a fence or other physical barriers’ to be the only type of measure available to a source in order to preclude public access in a practical or physical sense.”</p> <p>Furthermore, the EPA Revised Policy also explains:</p> <p>The EPA’s view is that the general public has legal access to areas that are owned and controlled by parties other than the owner or operator of a stationary source. The EPA continues to view the “general public” to include any person(s) other than those who are permitted access to the property as employees or business invitees of a specific stationary source (including trespassers).</p> <p>The Revised Policy also notes examples of “business invitees” such as “contractors or delivery persons.” In other words, people who are traveling on the Stibnite Road through the mine site to access public (Forest Service) property and who otherwise have no business dealings with Perpetua are members of the general public. Perpetua’s attempt to label the public as “guests of PRI” is disingenuous and should be considered, as stated in the Revised Policy, as an activity that “would expand the exclusion beyond reason and deny the protection of the NAAQS to large numbers of people.” Neither the EPA’s original 1980 Memo on ambient air or the 2019 Revised Memo expound to include semi-restricted members of the public or persons admitted under certain pretexts as those who can be excluded from the general public as Perpetua is attempting to do.</p> <p>The fact that these “guests” would apparently abide by access and safety procedures established by Perpetua is meaningless in terms of protecting the public from exposure to hazardous air conditions. In practical terms, there are no plans for air quality monitors on the road because it has been excluded from ambient air. Thus, it will not be known to those traveling on the road what type of acute exposure to air pollutants will result.</p> <p>Moreover, IDEQ’s own definition of “ambient air” is “[t]hat portion of the atmosphere, external to buildings, to which the general public has access.” The public access road through the project area fits that definition exactly. In addition, IDEQ’s Modeling Guidelines for determining the ambient air boundary demonstrate that this public road should not be excluded from the ambient air boundary:</p> <ul style="list-style-type: none"> ● It shall be assumed that the air within the facility boundaries is ambient air unless the facility can demonstrate that public access is precluded.” Here, although public access might be controlled, it will not be precluded according to the SDEIS. Thus, the road should not be excluded from an ambient air analysis. ● For the purpose of defining ambient air, the ‘general public’ is considered anyone not directly associated with the facility. In general, if someone present at the site would not be subject to OSHA or other worker exposure regulations, then they are considered as the general public.” People passing 	AIR	The USFS is accepting of the IDEQ interpretation of the ambient air boundary. Additionally, the EPA, while not explicitly endorsing this stance, has suggested language changes within the Final EIS to ensure to accurately portray the ambient air boundary definition.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>through the facility to access public land on the other side of the project area are not “directly associated with the facility” and would not be “subject to OSHA or other worker exposure regulations” and therefore are the general public.</p> <ul style="list-style-type: none"> • Is the general public allowed on site as a part of a right-of-way easement or a common service road? If “yes,” then the right-of-way is determined to be ambient air.” At this time, the public will be allowed access through the site. <p>Nevertheless, IDEQ appears to have contradicted their own rules and guidance and issued the IDEQ PTC excluding the Stibnite Road from ambient air controls. We contend that this action is an abuse of IDEQ regulatory discretion and this issue is currently being challenged in the aforementioned ICL/SSFS/NPT administrative appeal of the IDEQ PTC (IDEQ Case Docket No. 0101-22-02). While having agreement in analysis by all governing agencies regulating the permitting of the SGP is preferred, we do not believe IDEQ’s analysis should preclude the Forest Service from making a different, and more prudent, judgment.</p> <p>Finally, ICL acknowledges the feasibility analysis in which criteria pollutant modeling against the NAAQS was conducted for the Stibnite Road (SDEIS Air Specialist Report, page 80) and showed compliance. However, it is unclear why that SDEIS analysis made the conscious decisions to use the Qian and Venkatram modeling method while the NAAQS modeling analysis conducted for the rest of the SDEIS review used the BULKRN method and why HAP emissions (especially arsenic) were not considered in this analysis. Furthermore, considering the significant concerns associated with emissions calculations discussed above, the modeled impact of criteria pollutants within the Stibnite Road area may be flawed and under-representative of the true emissions.</p> <p>The Forest Service should coordinate with EPA and IDEQ to reassess the ambient air boundary determination and model ambient air concentrations along public access routes for both NAAQS and HAPs.</p>		
David Chambers	17641	5	<p>2.4.5.7 Ore Processing – Oxidation and Neutralization</p> <p>The autoclave is a major component of the ore processing system, yet doesn’t rate even a subtitled paragraph in the SDEIS, just a line here and there under other headings. An autoclave is very expensive to operate, requires pure oxygen from an oxygen plant, and because of the high operating temperature at which it operates, can be a major source of mercury in the exhaust. There is no discussion in the SDEIS about where the oxygen for the autoclave will be sourced. It must either be produced onsite in a local oxygen plant, which has potential hazards of its own, or it must be trucked in from an outside plant, with potential transportation liabilities. More information on the source and risks with oxygen must be provided.</p> <p>The potential for mercury air emissions is acknowledged in the SDEIS, and a short description of the mercury collection system that would be employed is briefly discussed in another section. There is probably potential for other contaminants to be present in the autoclave air emissions, for example particulate arsenic, but there is no discussion of other potential autoclave air emission contaminants.</p> <p>Any mercury in the ore processed in the autoclave is typically vaporized, and must be collected by an exhaust collection system. This collection system must be very efficient, because even at 99% efficiency enough mercury can escape to cause an air emission violation. Mercury was inadvertently discovered by the EPA in the early 2000s to be a major source of mercury emissions in autoclaves and roasters at mines in Nevada. These mines were emitting amounts of mercury equivalent to that from coal fired power plants, and at that time mercury emission controls for mines were not required and were not being utilized, even though the mines knew they were volatilizing significant amounts of mercury.</p> <p>Because the mercury emission control systems must operate at a very high efficiency in order to conform to air quality requirements, monitoring their performance is very important. There is no discussion of the efficiency at which these control systems must operate, or how and when they will be monitored.</p>	AIR	<p>The text has been revised to indicate that the autoclave system would be the equipment used for the oxidation step.</p> <p>Information regarding oxygen supply has been added to the Final EIS.</p> <p>The summary of predicted air pollutions presented in Section 4.3.2.2 includes autoclave system emissions.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			Autoclave operation needs to be given more importance than it presently receives in the SDEIS, and a thorough discussion of the monitoring for air emissions from the autoclave, mercury and any other potential contaminants, needs to be provided.		
Samuel Penney (Chairman)	19396	14	Clean, clear air is a critical component to ensuring the health and resiliency of the Tribe's treaty-reserved resources. Air pollution reduces visibility, which can impair cultural and ceremonial practices for Tribal members and reduce enjoyment of these special places. Air pollution causes a host of environmental and human health problems, including damage to culturally important plants, sensitive forests, and fish habitat, acidification of lakes and streams, depletion of soil nutrients, aggravated asthma, heart attacks, and premature death. Impacts can be especially harmful to at-risk ecosystems and especially harmful for sensitive human populations such as asthmatics, children, the elderly, people with diabetes, and people with heart or lung disease.	AIR	This comment is noted and the Final EIS describes the requirements here practicable.
Samuel Penney (Chairman)	19396	23	In Table 1.7-2 Key Permits, Approvals, and Regulation Compliance Likely Required, there is a permit missing. Under Idaho Department of Environmental Quality ("IDEQ") permits (on page 1-14), a Title V operating permit will be required once the 40 CFR 63 Subpart EEEEEEE - National Emission Standards for Hazardous Air Pollutants ("NESHAPs") for Gold Mine Ore Processing and Production Area Source Category units start up.	AIR	This was an inadvertent error. The Title V permit requirement has been added.
Samuel Penney (Chairman)	19396	48	To protect air quality after the SGP begins operations, the Forest Service relies on the state of Idaho's monitoring and enforcement of the SGP air permit to construct ("PTC"). However, the state of Idaho lacks the robust compliance assurance, monitoring, and enforcement resources that will be necessary to inspect and regulate such a facility in a remote location and ensure the SGP is meeting permit conditions and not violating the National Ambient Air Quality Standards ("NAAQS"). The minimum inspection frequency required of the air permit is once every five years. Given the extraordinary level of fugitive emissions controls necessary to achieve 93.3% control, and the State's own acknowledgement that this level of control will be very challenging ⁹⁴ , a once every five years inspection frequency is woefully inadequate to ensure NAAQS compliance.	AIR	As part of both the Final EIS and IDEQ PTC, mitigation measures specific to dust control would be required to ensure compliance with the 93.3%. Abatement measures would not be limited and a dust monitoring program is included as part of Final EIS.
Samuel Penney (Chairman)	19396	49	In Table 2.4-12 Prominent Regulatory and Forest Plan Requirements, the listed dust control level is incorrect. The text reads: "The Proponent will prepare a dust mitigation plan with appropriate schedule or triggers for control deemed adequate by IDEQ to achieve the level of control of 93 percent of dust (as submitted in the proponent's draft application for Permit to Construct from IDEQ)." The level of control in the IDEQ PTC is 93.3% to achieve necessary controls to protect NAAQS for Particulate Matter ("PM") ¹⁰ .	AIR	This table was reviewed and updated appropriately.
Samuel Penney (Chairman)	19396	49	Also in Table 2.4-12, there is a statement: "Alternatively, the proponent could employ particulate matter or opacity monitors deemed adequate by IDEQ and the Forest Service and immediately apply water or chemical dust control when PM or opacity monitors reach levels within 10 percent of the threshold determined by IDEQ." ⁹⁷ Employing monitors is not a valid or allowable alternative for controlling dust on haul roads in the PTC. "Alternatively" should be replaced with "Additionally".	AIR	Need to refer to the source of the 93.3% control efficiency. It was determined based upon conservative modeling. Realtime monitoring should be able to confirm whether the 93.3% efficiency is protective, or whether a higher/lower control efficiency is needed/sufficient. Dust monitoring is also being incorporated in the Final EIS as a mitigation measure.
Samuel Penney (Chairman)	19396	50	Also in Table 2.4-12, there is a statement: "Dust abatement chemicals would be used in accordance with the applicable road maintenance Biological Assessment." ⁹⁸ There may be a potential conflict with meeting 93.3% dust control efficiency criteria on haul roads if use of dust abatement chemicals is limited.	AIR	As part of both the Final EIS and IDEQ PTC, mitigation measures specific to dust control would be required to ensure compliance with the 93.3%. Abatement measures would not be limited and a dust monitoring program is included as part of Final EIS.
Samuel Penney (Chairman)	19396	51	Table 2.4-13 Proponent Proposed Design Features lists the environmental design features (EDFs) beyond regulatory requirements that have been proposed and committed to by Perpetua. A "commitment" is not a mitigation requirement unless it's included as an actual, specific mitigation in the EIS and as an actual, specific permit requirement. For example, the first item in Table 2.4-13 is, "Following crushing, the crushed ore would report via conveyor to a dome-shaped, covered stockpile." ⁹⁹ Perpetua withdrew covered stockpiles from its application for the PTC, and covered stockpiles are not included in the PTC, so Perpetua is not required to have covered ore stockpiles as a condition of the PTC. Another EDF is, "Proper dust control would be employed along transportation	AIR	All mitigation requirements are incorporated into the Final EIS in Section 4.3.5. Covered stockpiles are included for ore. The low-grade stockpiles and feed pile prior to the crusher are uncovered. This was included in the table as such. Dust control measures are incorporated into the Final EIS and dust monitoring has been added. This a measure to ensure design features are being met. The Tier IV highway engines are required as mitigation measure.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			corridors and active mining areas using aquatic safe dust suppression chemicals and methods.”100 The Forest Service does not specify what proper dust control means (by including specific timing of measurement, application of controls, and recordkeeping requirements). Another listed EDF is, “All off highway diesel engines would be EPA Tier 4 or better.”101 The EDFs listed in the SDEIS are unenforceable unless included as mitigation measures and as permit requirements. The Forest Service should include all EDFs as mitigation measures.		
Samuel Penney (Chairman)	19396	54	<p>2.8 Summary Comparison</p> <p>In Table 2.8-1 Alternative Comparison and Impact Summary the Forest Service does not disclose in the SDEIS that the ambient air within the Operation Area Boundary is not subject to meeting the NAAQS. Under the Clean Air Act, air permits and their specific enforceable provisions (e.g. air pollution control equipment, dust control plans, operational limits, etc.) are intended to ensure that NAAQS are not violated, but this only applies outside of a facility’s operations area boundary.</p> <p>Air permits will not protect the Tribe’s treaty-reserved rights and numerous cultural resources within the operational boundary. Trust responsibilities extend to all life, plants and animals that can’t speak for themselves. The SDEIS does not address the issue of NAAQS exceedances inside the operations area boundary.</p>	AIR	As the comment states, the NAAQS are intended to comply at the Project boundary and beyond. While there is no explicit NAAQS compliance within the Project boundary, OSHA compliance is required. Additionally, the permit/Final EIS requires controls to minimize emissions as much as practicable. Following the Project, restoration would occur as well. The treaty-reserved rights are outlined in Sections 3.24 and 4.24 of the Final EIS.
Samuel Penney (Chairman)	19396	72	<p>3.3 Air Quality</p> <p>The public access road between Stibnite Road at Sugar Creek and Thunder Mountain Road at Meadow Creek should not be excluded from the regulatory definition of ambient air. This road is intended to allow public access, not preclude it. EPA’s revised Ambient Air Policy describes conditions by which the public is to be excluded from an area controlled by a source and which would then justify excluding an area for purposes of analyzing the source’s impact on ambient air.</p> <p>Controlling public access through a site is not excluding public access through a site, thus the EPA revised Ambient Air Policy does not apply, and therefore, the public access road should be considered ambient air. As the public access road is ambient air, all emissions, modeling, and controls must be characterized and considered and are subject to the NAAQS.</p>	AIR	IDEQ has deemed the access road to be precluded from the ambient air boundary. This is because Perpetua has complete control over the road and it is not considered "public". USFS has considered IDEQ's determination to be appropriate. Also, the EPA has referenced the application the Revised Policy in their comments to the SEIS. The EPA requested language regarding the EPA position on use of the public access road through the mine site has been included in the Final EIS.
Samuel Penney (Chairman)	19396	73	The statement, “A determination was made by the IDEQ that the SGP would not require a Title V permit” is erroneous. Once 40 C.F.R. 63 Subpart EEEEEEE (NESHAPs: Gold Mine Ore Processing and Production Area Source Category) units start up, IDEQ requires a Title V operating permit.	AIR	This was an inadvertent error. The Title V permit requirement will be added.
Samuel Penney (Chairman)	19396	74	In Table 3.3-4 Visibility Impairment and Deposition-Related Monitoring Sites, the table contains an error. The Tribe’s Clean Air Status and Trends Network (“CASTNET”) site, NPT006, started in 2015 not 2002. Also, the Table 3.3-9 CASTNET Dry Deposition Rates, Annual Average – Two Idaho Sites and Figure 3.3-7 Trends in Dry Nitrogen and Sulfur Deposition Rates, 2006-2015, include data prior to 2015 for the Tribe’s CASTNET site, NPT006. This is not possible because the site was not sampling prior to 2015.	AIR	While the current version of NPT006 was installed in 2015, Stantec communicated with the EPA, CASTNET team. A measurement-model fusion approach for calculating deposition was applied. When measurement concentrations (or fluxes for wet deposition) are available those are used. Otherwise, a modeled value is used. The NPT006 deposition values are from the CMAQ grid for this location from 2000-2015 prior to the site installation. See https://nadp.slh.wisc.edu/committees/tdep/ for more details. That said, the data in Table 3.3-9 doesn't appear to match the information provided on the CATNET site. The data will be updated appropriately in the Final EIS. Also, Table 3.3-7 is the Reynolds Creek site and has nothing to do with NPT006.
Samuel Penney (Chairman)	19396	172	The Forest Service relies on the IDEQ air permit for assuring requirements under the Clean Air Act are met.335 There are several issues with this. First, the Forest Service cannot claim as mitigation measures state of Idaho PTC plans that have not yet been finalized. The PTC’s Fugitive Dust Control Plan, Operations and Maintenance Plan, Access Management Plan, and Haul Road Capping Plan, although referenced in the PTC, have not yet been written, and will not be subject to a public comment process. The Forest Service must clearly identify mitigation measures in the SDEIS necessary to minimize the Project’s adverse impacts to the environment.	AIR	All the various management plans outlined in the PTC will be completed prior to completion of the Final EIS and included or will be required to get USFS approval prior to the commencement of construction. The Final EIS includes numerous mitigation measures not previously outlined in the SDEIS, one of which includes a dust monitoring program.
Samuel Penney (Chairman)	19396	166	Second, the Forest Service does not address fugitive dust control measures on the Project access roads into the mine (outside of the mining operations boundary). The fugitive dust control plan in the Environmental Monitoring and Management Program does not specify dust control requirements (by	AIR	The Final EIS addresses fugitive dust control measures specifically in Section 4.3.5 and 7.3 of the Air Quality Specialist Report. Additionally, the PTC, requires the FDCP to be approved

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			including specific timing of measurement, application of controls, and recordkeeping) and is, therefore, inadequate to protect the NAAQS and avoid sedimentation of adjacent waterways. The Forest should clearly state specific, detailed fugitive dust control requirements for mitigation of adverse environmental impacts.		prior to construction. The USFS will either include the FCDP with the Final EIS or also require approval prior to construction.
Samuel Penney (Chairman)	19396	167	Third, as we have also commented regarding the SDEIS (at 2-136 and 2-137) and the Air Quality Specialist Report (at p.1), under the Clean Air Act, air permits and their specific enforceable provisions (e.g., air pollution control equipment, dust control plans, operational limits, etc.) are intended to ensure that NAAQS are not violated, but this only applies outside of a facility's operations area boundary. Even with a well-developed, data-supported, practically enforceable air permit, within that operational boundary (aside from the specific question the Tribe has raised about the public access road being ambient air), a facility is allowed to exceed the NAAQS. Any air permit, therefore, will not protect the Tribe's treaty-reserved rights and numerous cultural resources within the operational boundary. Trust responsibilities extend to all life, plants, and animals that cannot speak for themselves. The SDEIS does not address the issue of NAAQS exceedances inside the operations area boundary.	AIR	As the comment states, the NAAQS are intended to comply at the Project boundary and beyond. While there is no explicit NAAQS compliance within the Project boundary, OSHA compliance is required. Additionally, the permit/Final EIS requires controls to minimize emissions as much as practicable. Following the Project, restoration would occur as well. Regarding tribal rights issues, please refer to sections 3.24 and 4.24 of the Final EIS.
Samuel Penney (Chairman)	19396	168	The public access road between Stibnite Road at Sugar Creek and Thunder Mountain Road at Meadow Creek should not be excluded from the regulatory definition of ambient air. This road is intended to allow public access, not preclude it. EPA's revised Ambient Air Policy describes conditions by which the public is to be excluded from an area controlled by a source and which would then justify excluding an area for purposes of analyzing the source's impact on ambient air. Controlling public access through a site is not excluding public access through a site, thus the EPA revised Ambient Air Policy does not apply, and, therefore, the public access road should be considered ambient air. As the public access road is ambient air, all emissions, modeling, and controls must be characterized and considered, and subject to the NAAQS.	AIR	IDEQ has deemed the access road to be precluded from the ambient air boundary. This is because Perpetua has complete control over the road and it is not considered "public". USFS has considered IDEQ's determination to be appropriate. Also, the EPA has referenced the application the Revised Policy in their comments to the SEIS. The EPA requested language regarding the EPA position on use of the public access road through the mine site has been included in the Final EIS.
Samuel Penney (Chairman)	19396	169	Table 4.3-20 SGP Public Access Route Receptor Results and NAAQS Compliance Demonstration shows compliance with the NAAQS. The values in Table 4.3-20 come from a 2021 report by Air Sciences, Inc. However, the public access road modeling in the Air Sciences 2018 report showed PM10 and PM2.5 NAAQS exceedances using the site-specific meteorological data set BULKRN. In the SDEIS, the Forest Service has chosen to present only the 2021 modeling results in Table 4.3-20, which had no exceedances and used the Q&V meteorological data set. This is not an accurate representation of modeling results. Both the 2018 and 2021 data sets are valid, so all data should be presented.	AIR	The 2018 AQ Report was representative of the initial ModPro Proposed Action, which was modified in lieu of the 2021 ModPro2 action. ModPro is no longer an alternative being considered. Therefore, use of the 2018 results are no longer pertinent to the Project and its inclusion in the Final EIS is not relevant. Additionally, the projected PM2.5/10 emissions from the worst-case year of ModPro2 are less than those from ModPro. It should be noted that the only potential exceedances from the 2018 analysis occurred along the access road, which was deemed to be excluded from ambient air by IDEQ and accepted by USFS. Lastly, the Q&V method is the default meteorological data (onsite from 2014) approach typically used within AERMOD and acceptable to be applied. The IDEQ Statement of Basis, Section 4.1.4 outlines a "weight of evidence" claim that use on NON-BULKRN is acceptable for numerous reasons. First, the standard is the 2 nd high, but background used assumed the first high. Second, when using BULKRN, the results are limited to a small area and limited period of time. Next, the exceedances are limited to the winter season among other conservative assumptions. Collectively, IDEQ states that they are highly confident that SGP will not contribute to a violation of the NAAQS. Also, the EPA evaluated Adj_U* and Q&V b in a series of studies comparing modeling vs observed. As illustrated in Table 69 of the 2018 ASI modeling report, all locations suggested conservative results. Ultimately, while there may be sporadic receptors using BULKRN that suggest an exceedance, but layers of built in conservatism suggests the results are artificially high.
Samuel Penney (Chairman)	19396	405	5.3 Air Quality On page 5-14 of the SDEIS, the Forest Service states, "Overall, air emissions are expected to increase as a result of the SGP and the past, present, and future actions. However, these emissions would be regulated in accordance with State and federal air permitting requirements." As the Tribe has commented previously in this letter regarding the SDEIS (at 2-136 & 4-35) and the Air Quality	AIR	As the comment states, the NAAQS are intended to comply at the Project boundary and beyond. While there is no explicit NAAQS compliance within the Project boundary, OSHA compliance is required. Additionally, the permit/Final EIS requires controls to minimize emissions as much as practicable. Following the Project, restoration would occur as well. Tribe's treaty-reserved rights" are discussed in Sections 3.24 and 4.24 of Final EIS. Mitigation measures will be outlined in Section 4.3.5 of the Final EIS.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			Specialist Report (p.1), the Forest Service’s reliance on air permitting requirements is inadequate to protect air quality and the Tribe’s treaty-reserved rights and cultural resources.		
Samuel Penney (Chairman)	19396	431	<p>Air Quality Specialist Report</p> <p>The introduction of the Air Quality Specialist Report does not acknowledge air protection to the environment (secondary NAAQS).⁶⁴⁵ Only human health impacts are discussed (primary NAAQS). The affected environment is then portrayed as near-field or far-field. Under the Clean Air Act, air permits and their specific enforceable provisions (e.g., air pollution control equipment, dust control plans, operational limits, etc.) are intended to ensure that NAAQS are not violated, but this only applies outside of a facility’s operations area boundary. Even with a well-developed, data-supported, practically enforceable air permit, within that operational boundary (aside from the specific question the Tribe has raised about the public access road being ambient air), a facility is allowed to exceed the NAAQS. Any air permit, therefore, will not protect the Tribe’s treaty reserved rights and numerous cultural resources within the operational boundary. Trust responsibilities extend to all life, plants and animals that can’t speak for themselves. The SDEIS does not address the issue of NAAQS exceedances inside the operations area boundary.</p>	AIR	<p>The secondary results shown in Table 4.3-20 demonstrate compliance with both the primary and secondary NAAQS at the project boundary and beyond. The exception being lead and 24-hr PM2.5. There are no expected lead emissions and primary 24-hr PM2.5 standard is met, thus ensuring the secondary is as well. That said, a brief discussion of secondary NAAQS has been added to the Air Quality Specialist Report for context and understanding. In addition, the NAAQS are intended to comply at the Project boundary and beyond. While there is no explicit NAAQS compliance within the Project boundary, OSHA compliance is required. Additionally, the permit/Final EIS requires controls to minimize emissions as much as practicable. Following the Project, restoration would occur as well.</p> <p>“Tribe’s treaty-reserved rights” are discussed in Sections 3.24 and 4.24 of Final EIS.</p>
Samuel Penney (Chairman)	19396	432	<p>The information included in the Air Quality Specialist Report and the SDEIS is inconsistent. Some information about air quality in the Air Quality Specialist Report is not included in the SDEIS, and some information about air quality in the SDEIS is not included in the Air Quality Specialist Report. This can be clearly seen when comparing Tables 2.4-12 and 2.4-13 of the SDEIS with Tables 2-2 and 2-3 in the Air Quality Specialist Report. For example, the Air Quality Specialist Report Table 2-2 Prominent Regulatory and Forest Plan Requirements for Air Quality includes “Deploy a satellite or network connected visibility web camera as part of the FS visibility network aimed from the boundary of Frank Church River of No Return Wilderness (“FCRNRW”) south of mine across to FCRNRW boundary north of mine and/or from north to south on the FCRNRW boundary looking to the opposite boundary to document frequency of plume blight and visibility impacts to the wilderness area”, but this requirement is missing in the SDEIS. Additionally, in the SDEIS Table 2.4-13 Proponent Proposed Design Features, “Dust emission controls would reduce dust from crushing, conveying, and stockpiling” is listed, but is not included in the Air Quality Specialist Report. With these inconsistencies it is not clear what requirements the USFS is really proposing. All requirements should be in both locations.</p> <p>The reference for the Fugitive Dust Control Plan listed on page 13 is not listed in the reference section and Forest Service personnel could not provide the document when asked. The Forest Service must include an actual fugitive dust control plan as a mitigation measure for the project.</p> <p>The statement “On June 17, 2022 IDEQ issued a final Permit to Construct (“PTC”) and Statement of Basis (“SOB”) stating that the SGP will not require a Title V permit”⁶⁴⁶ is not true, see IDEQ 2022, Statement of Basis, Permit to Construct No. P-2019.0047, Project ID 62288, Perpetua Resources Idaho, Inc. Stibnite, Idaho Facility ID 085-00011.</p>	AIR	<p>There will be some variability between the EIS and the Air Quality Specialist Report. The EIS is intended to capture the general tenure of the requirements, while the Specialist Report goes into much greater detail. That said, any inconsistencies amongst the documents will be reviewed and updated as appropriate. The reference of a Title V permit not being required was an error and has been updated. The reference in the SDEIS of the FDCP was an error. At the time of the development of the SEIS, the FDCP was thought to exist and was referenced. However, it was later determined that the document has yet to be developed. It would be developed prior to the commencement of construction with USFS approval.</p>
Samuel Penney (Chairman)	19396	433	<p>The Air Quality Specialist Report states on page 63, “The main ore processing facility building, and coarse ore stockpile would be enclosed.” This is incorrect. There is no requirement in the PTC for the ore stockpiles to be enclosed.</p>	AIR	<p>The Final EIS has that requirement regardless of the PTC requirements. See Section 4.3.5.</p>
Samuel Penney (Chairman)	19396	434	<p>The Air Quality Specialist Report states on page 3-20 of Appendix D, “The EPMS would target maintaining a control efficiency of 90 percent on the on-site haul roads.” This is incorrect. In the IDEQ PTC, the control efficiency for haul roads is 93.3% for haul roads.</p>	AIR	<p>The comment is correct. The Air Quality Specialist Report, Transportation Plan (Appendix D), has been updated.</p>

Climate Change

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Elizabeth Barnes	6652	5	p. 2-145 The loss of wetlands through drawdown or direct disturbance from mine construction (119 acres stated) is not included in the climate change impacts assessment. A low-end estimate of the carbon stored by wetlands is 81 metric tons (The Conservation Fund) per acre. Loss of these 119 acres in the SGP area could contribute up to 9,639 T of carbon, equivalent to 25,000 T CO ₂ , to the atmosphere via leaching, oxidation, and rapid decomposition. Considering a truck emits 160 grams CO ₂ per mile, this loss of wetland-stored carbon is equivalent to driving a truck over 100 million miles, making the climate change assessment, that is based on engine combustion alone, completely irrelevant. Other impacts to climate change not addressed in the analysis are rock blasting, which is a significant source of NO ₂ and CO ₂ not accounted for in the GHG analysis.	CLI	There is variability in carbon storage values of wetlands depending on the location. While the values provided in the comment are mathematically sound it is unclear whether that represents the state of Idaho. Regardless, by the end of the Project, all wetlands would be restored (reclaimed) and eventually the storage amount would be a net zero. Because the effects of climate change is on a much longer timescale it is expected that the increased CO ₂ released would be temporary in nature. That said, this discussion has been added to the indirect emissions section of the Final EIS. The source of blasting emission factor applied should have included methane (EPA AP-42, Section 13.3-1). NO ₂ emissions are determined to be non-detectable. This has been added to the Final EIS. Canada Mining Guidance has a CO ₂ EF of 0.189 kg/kg AFO.
Elizabeth Barnes	6652	23	4-220 Climate change analysis does not include gaseous emissions predicted by the 2 stage alkaline treatment for cyanide reduction. Why not?	CLI	Alkaline treatment for cyanide reduction is a component of the emissions analysis developed for the processing plant and is included in that calculation.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	31	4. CEQ guidance on climate change In addition to the comments below, the Forest Service must incorporate CEQ's recent interim guidance to assist federal agencies in analyzing greenhouse gas emissions and climate change effects of their proposed actions under NEPA. ⁵⁹ As CEQ poignantly reminds all federal agencies: Given the urgency of the climate crisis and NEPA's important role in providing critical information to decision makers and the public, NEPA reviews should quantify proposed actions' GHG emissions, place GHG emissions in appropriate context and disclose relevant GHG emissions and relevant climate impacts, and identify alternatives and mitigation measures to avoid or reduce GHG emissions. CEQ encourages agencies to mitigate GHG emissions associated with their proposed actions to the greatest extent possible, consistent with national, science-based GHG reduction policies established to avoid the worst impacts of climate change.	CLI	On January 9, 2023, the Council on Environmental Quality (CEQ) published interim "National Environmental Policy Act Guidance on Consideration of Greenhouse Gas Emissions and Climate Change" in the Federal Register (CEQ 2023). CEQ grants agencies the discretion to decide whether to apply the guidance to NEPA analyses that were in progress when the guidance was issued. The interim CEQ guidance was published late in the development process for the SGP DSEIS, and therefore this EIS primarily relies on earlier CEQ guidance on considering climate change in NEPA (CEQ 2016). For example, this EIS does not include all new recommendations such as applying social cost of GHG estimates to the incremental metric tons of each individual type of GHG emissions expected from the Proposed Action and its alternatives. However, this EIS does analyze the two fundamental considerations required by current and former iterations of CEQ climate change guidance: (1) the potential effects of a proposed action on climate change, including both GHG emissions and reductions from the proposed action (see below), and (2) the effects of climate change on the proposed action and its environmental impacts.
Idaho Regulatory Agencies	17718	4	Please provide facts on how closure and reclamation could reduce climate change impacts and improvement of soil quality.	CLI	In its current unreclaimed condition, the site exhibits poor soil and revegetation conditions. Effective reclamation and closure would improve soil and revegetation conditions, allowing for carbon dioxide use by re-established vegetation. The Climate Change Specialist Report discusses reclamation in Section 7.2.2.2. The SDEIS Sections 3.5/4.5 outline soils/reclamation materials. Sections 3.10/4.10 provide discussion on vegetation.
Giles, Robertt (Mayor McCall, ID)	17834	13	Attached is a memo describing the City's concerns with the lack of recognition by the Forest Service of the magnitude of impact from the mine's operations on creation of GHG's and the resulting externality created by not requiring mitigation by the company. Those costs will be shifted onto the local communities working to reduce GHG's. The company's GHG generation will substantially outweigh our local efforts to reduce emissions. The City requests that a second supplemental DEIS identify mitigations to address the mine's impact on our regional climate.	CLI	Comment noted. See the response to comment 17834.35 which provides specific inquiries on GHG generation. Also, for CEQ Guidance, timeline and applicability see comment 17634.31.
Giles, Robertt (Mayor McCall, ID)	17834	35	Summary: McCall is a diverse, small town united to maintain a safe, clean, healthy, and attractive environment. It is a progressive community that is affordable and sustainable. There are specific unknowns that should be addressed within the DEIS Climate Change Specialist Report to allow for the City of McCall and our community to best actualize our vision. This memorandum focuses on the need for a thoroughly conducted analysis of the influence of the SGP on climate change through a greenhouse gas emissions analysis and inclusion of common climate mitigation solutions available to Perpetua/SGP to address the relevance of the following: 1) Data Analysis: There is a need for accurate regional measurements and statistics that can alter the long-range needs for City infrastructure planning - including our own efforts as a municipality to mitigate climate change impacts occurring within our city boundaries and beyond city boundaries – these	CLI	Section 4.4.2.2 analyzes the two fundamental considerations required by current and former iterations of CEQ climate change guidance: (1) the potential effects of a proposed action on climate change, including both GHG emissions and reductions from the proposed action, and (2) the effects of climate change on the proposed action and its environmental impacts. These include energy usage by the Project as a customer of Idaho Power Company and the LCA on antimony transport. Additionally, the Climate Change Specialist report discusses these items in Section 7.2.2.1. Vehicle trips between the mine site and local grocery stores, schools, etc. are not part of the Project as proposed under the 2021 MMP. Site workers would reside on-site through their shifts and road travel off-site would occur under exceptional circumstances.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>data and mitigation projections are essential to our operations to best serve our residents, businesses and workforce;</p> <p>2) Energy Use & Infrastructure: The impacts anticipated on the local/regional power-grid customers given the large increase in energy demand that is likely to influence rates for city energy users if no additional energy generation infrastructure is provided by SGP/Perpetua to offset the increase in demand estimated within the DEIS Specialist Report. Any new generation requirements should be in the form of renewable energy in order to mitigate climate impacts.</p> <p>3) Climate Mitigation Opportunities: There is some likelihood of lost opportunity for the City and greater community to benefit from climate change impact mitigation, or “environmental design features” on the part of SGP/Perpetua in the 2021 MMP with no mitigation of substance proposed at this time. Reasonable mitigation that aims to be aligned with IPCC recommendations and adequately addresses climate change should likely include investment in off-site emissions mitigation given the scale and intensity of emissions generated by the proposed project (direct, indirect and not-yet-measured); We would respectfully request an inventory of both the “No Action” Alternative and 2021 MMP Alternative, identified as preferred by the USFS.</p> <p>1) Data Analysis: The Climate Change Specialist Report for the SGP DEIS states “the 2021 MMP has the potential to impact public health and safety through the transportation and use of fuel and chemicals, natural environmental hazards, economic impacts, changes to public services and infrastructure, and impacts to the local population” (p. 37, Payette & Boise National Forest, 2022). In relation to climate change, each of these sectors cited to be potentially impacted have measurable climate related impacts that were not adequately assessed through an accurate greenhouse gas emissions analysis including all standard scopes of measurement. As of March 2022, at least 194 gold mines across 35 countries have conducted accurate Greenhouse Gas Emissions Inventories in accordance with the World Resource Institute’s Global Protocol for Corporate GHG Accounting & Reporting (Fimmano, 2022; Ranganathan et al., 2015). At this time, the greenhouse gas emissions analysis conducted has a scope that is limited beyond the accepted methodology for emissions accounting and does not provide the data necessary for the city to measure and mitigate the emissions sources and activities likely to be added to the community by the SGP proposal. Unknowns relating to necessary, measurable data that are essential to the City’s goals of mitigating climate change are summarized as follows:</p> <ul style="list-style-type: none"> · Transportation: The DEIS Climate Report only identifies the Vehicle Miles Traveled (VMT) along the access road from Highway 55 to the Central Mining Site. There is reference to trip generation, vehicle miles traveled, and infrastructure use in regional cities (including the City of McCall), but there is no report or attempt to quantify this usage of McCall/McCall Area Roadways, Service Stations, or other facilities that is acknowledged within this Climate Report. Common metrics in transportation that should be projected would include, but not be limited to: § Frequency and distance travelled of SGP/Perpetua workforce members living on-site traveling to <ul style="list-style-type: none"> · Grocery stores in McCall · schools where workforce members children may attend · activity/recreation areas and offerings in McCall § Frequency and distance travelled of SGP/Perpetua workforce members living off-site, outside of McCall City Limits traveling to <ul style="list-style-type: none"> · SGP Transfer Site off Highway-55 or SGP Main Site · Grocery stores in McCall · schools where workforce members children may attend · activity/recreation areas and offerings in McCall 		<p>Road travel associated with SGP employees during their non-work time is outside the scope of the analysis.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>§ Frequency and distance travelled of SGP/Perpetua workforce members living off-site, inside of McCall City Limits traveling to</p> <ul style="list-style-type: none"> · SGP Transfer Site off Highway-55 or SGP Main Site · Grocery stores in McCall · schools where workforce members children may attend · activity/recreation areas and offerings in McCall <p>It is also unclear based on the provided Fleet Vehicle and Commuting analysis whether the fuel efficiencies and types analyzed reflect the actual vehicles that are likely to be on the market and road 20-40 years into the future, the proposed lifespan of SGP.</p> <p>2) Energy Use & Infrastructure: The DEIS Climate Report provides a rough estimate of Energy Use/Emissions potential totaling roughly 394,200 MWh (or ~45MW) of energy demand that would be added to the existing Idaho Power grid with no additional generation proposed. This is an approximate annual emissions amount of ~97,000 Tons of CO2e being added to our region’s emissions that does not currently exist (Payette & Boise National Forest, 2022). The ‘Indirect’ energy-use-driven emissions are not identified as actionable for mitigation within the SGP “Environmental Design Features,” however, energy mitigation is one of the most common environmental mitigation actions available to Gold Mines due to the high impact of grid-tied energy on overall project emissions. If the correct GHG Emissions Analysis Protocol cited previously were pursued, these emissions would fall into the category of “Scope 2” emissions (Ranganathan et al., 2015; Chaplin, 2022). For context, the addition of 45 MW of energy demand to the grid we share is the equivalent amount of energy generated by a 280-acre solar-farm.</p> <p>Without addition of energy generation to the Idaho Power Grid to mitigate the additional demand and mitigate resulting emissions, the increase in grid-based emissions would be the responsibility and financial burden of Idaho Power Customers, including the City and its residents to solve.</p> <ul style="list-style-type: none"> · Local Infrastructure Demand: It is unknown at this time to what extent the SGP proposals may increase demand for new housing, transportation, commercial, or public health infrastructure. If these socio-economic variables have been quantified elsewhere, they should be analyzed within the SGP Greenhouse Gas Emissions Analysis as direct additions to the City’s Greenhouse Gas Emissions Inventory for the projected LOM. <p>3) Climate Mitigation Opportunities: Without an accurate, quantitative Greenhouse Gas Emissions Analysis included that addresses the measurable and crucial variables identified above, as well as other sources and activities described within the leading methodologies (including Scope 1 – Direct/Source based emissions; Scope 2 – Indirect/Activity-based emissions; and Scope 3 – Sources & Activities within the complete supply chain) it is likely that common and attainable climate change and greenhouse gas mitigation projects will not be available that would likely benefit the City in efforts to achieve our climate mitigation goals. The (under)estimated total emissions of SGP under the MMP 2021 scenario are cited as at least 301,845 Tons of CO2e per year (mean; average) throughout the LOM. The “Environmental Design Features” proposed by Perpetua/SGP to address climate change appear at present to include only:</p> <ul style="list-style-type: none"> · “All off-highway diesel engines would be EPA Tier IV or better” · “Perpetua would utilize ‘smart grid’ technology to reduce energy consumption, such as auto dimming lights in offices.” <p>These design features do not include a projected amount of GHG Mitigation over the LOM or annually, although it is possible to project these with a complete analysis (p. 9, Payette & Boise National Forest, 2022).</p> <p>It is likely that if SGP/Perpetua were to be required to mitigate GHG Emissions generated by the real Scope 1 and Scope 2 emissions tied directly to emissions that would not otherwise be generated without</p>		

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>SGP (in reference to the No Action Alternative), mitigation should be required through both on-site and off-site strategies to account for the scale of emissions generated (Ranganathan et al., 2015). The City of McCall and other regional entities would seek to gain substantially from a data-driven requirement for off-site climate mitigation strategies such as the generation of new renewable energy to mitigate new energy demand related to SGP; and investment in zero-carbon transportation infrastructure such as funding public electric vehicle charging, provision of electric public transportation and protection of our water supply, stream beds, and regional ecosystems to mitigate emissions beyond those generated by energy use, to name a common few.</p> <p>Conclusion: The Climate Change Specialist Report on the proposed impacts of the Stibnite Gold Project on the local climate system acknowledges there will be greenhouse gas emissions inherent to the operations of the proposed mine. However, it inaccurately suggests that these measurable impacts, some identified and some yet-to-be-identified, are either not worth measuring or not essential to mitigate because climate change itself is a global phenomenon. This analysis does not consider the responsibility and initiative being taken by cities such as the City of McCall, and broader communities such as our own for mitigating the greenhouse gas emissions that we generate directly and indirectly as part of the broader regional, state, federal and global systems that drive and are already impacted by the early effects of climate change. Without the acknowledgement of responsibility for and commitment to mitigating measurable/proposed emissions, the MMP 2021 is likely to at least double the efforts necessary for the City of McCall and broader community to mitigate our regional greenhouse gas emissions if approved, in comparison to the No Action Alternative.</p> <p>It should be clearly stated that without an accurate and comprehensive greenhouse gas emissions analysis for the proposed Lifetime of Mine and subsequent Water Treatment timeline, and without requirement for mitigation of the GHG emissions added to the current levels, it is unlikely that the City of McCall or neighboring communities will benefit from climate & GHG mitigation initiatives that should be provided by Perpetua/SGP. Instead, the addition of these unmitigated emissions (lifetime emissions of at least 4,996,546 Metric Tons CO₂e over the 20 year LOM) to our broader community emissions portfolio, will fall on the shoulders of the City of McCall, neighboring Cities, and the Valley County community at large to address.</p>		
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	10	<p>For climate change:</p> <ul style="list-style-type: none"> o Including science-based greenhouse gas emissions reduction targets. o Assessing the social cost of carbon. o Incorporating adaptation in project features, such as stream crossings, reconstruction, and riparian cover. 	CLI	On January 9, 2023, the Council on Environmental Quality (CEQ) published interim “National Environmental Policy Act Guidance on Consideration of Greenhouse Gas Emissions and Climate Change” in the Federal Register (CEQ 2023). CEQ grants agencies the discretion to decide whether to apply the guidance to NEPA analyses that were in progress when the guidance was issued. The interim CEQ guidance was published late in the development process for the SGP DSEIS, and therefore this EIS primarily relies on earlier CEQ guidance on considering climate change in NEPA (CEQ 2016). For example, this EIS does not include all new recommendations such as applying social cost of GHG estimates to the incremental metric tons of each individual type of GHG emissions expected from the Proposed Action and its alternatives. 			recommends the FEIS apply the interim guidance as appropriate, to ensure robust consideration of potential climate impacts, mitigation, and adaptation issues.		Proposed Action and its alternatives. However, this EIS does analyze the two fundamental considerations required by current and former iterations of CEQ climate change guidance: (1) the potential effects of a proposed action on climate change, including both GHG emissions and reductions from the proposed action (see below), and (2) the effects of climate change on the proposed action and its environmental impacts.
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	57	<p>Science-based GHG Reductions Targets</p> <p>The analysis in the DSEIS compares project emissions to Idaho state-level emissions as a percentage. EPA recommends the FEIS compare project emissions to science based GHG reductions targets. The United States has established a Paris-agreement target to reduce net GHG emissions economy-wide by 50-52% below 2005 levels, consistent with a pathway to net-zero by 2050. EO 14057 establishes a policy for the federal government to lead by example in order to achieve a carbon-pollution free electricity sector by 2035 and net-zero emissions economy-wide by no later than 2050. These and other policies reflect science based GHG reduction goals to avoid the worst impacts of climate change.</p> <p>EPA recommends the FEIS discussion include whether and to what extent the estimated GHG emissions from the proposed alternatives are consistent with achieving these science based national GHG reduction targets and any relevant state or local goals.</p>	CLI	On January 9, 2023, the Council on Environmental Quality (CEQ) published interim “National Environmental Policy Act Guidance on Consideration of Greenhouse Gas Emissions and Climate Change” in the Federal Register (CEQ 2023). CEQ grants agencies the discretion to decide whether to apply the guidance to NEPA analyses that were in progress when the guidance was issued. The interim CEQ guidance was published late in the development process for the SGP DSEIS, and therefore this EIS primarily relies on earlier CEQ guidance on considering climate change in NEPA (CEQ 2016). For example, this EIS does not include all new recommendations such as applying social cost of GHG estimates to the incremental metric tons of each individual type of GHG emissions expected from the Proposed Action and its alternatives. However, this EIS does analyze the two fundamental considerations required by current and former iterations of CEQ climate change guidance: (1) the potential effects of a proposed action on climate change, including both GHG emissions and reductions from the proposed action (see below), and (2) the effects of climate change on the proposed action and its environmental impacts.
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	58	<p>Social Cost of Carbon</p> <p>The DSEIS notes “[f]or purposes of this analysis, qualitative analysis is appropriate because quantifying the relative costs and benefits of the alternatives is not practically feasible and would be subject to high uncertainty as described below.” However, the DSEIS calculates estimates of direct and indirect emissions, and these estimates can be used to monetize those emissions using the Social Cost of Greenhouse Gases (SG-GHG). EPA encourages lead agencies to monetize impacts of GHG emissions using SG-GHG estimates in NEPA analyses. For transparency, EPA recommends the FEIS assess the climate impacts and disclose climate damages of the proposed project using the SC-GHG, which reflect the best available science and methodologies to monetize the value of net changes in direct and indirect GHG emissions resulting from a proposed action to society.</p>	CLI	On January 9, 2023, the Council on Environmental Quality (CEQ) published interim “National Environmental Policy Act Guidance on Consideration of Greenhouse Gas Emissions and Climate Change” in the Federal Register (CEQ 2023). CEQ grants agencies the discretion to decide whether to apply the guidance to NEPA analyses that were in progress when the guidance was issued. The interim CEQ guidance was published late in the development process for the SGP DSEIS, and therefore this EIS primarily relies on earlier CEQ guidance on considering climate change in NEPA (CEQ 2016). For example, this EIS does not include all new recommendations such as applying social cost of GHG estimates to the incremental metric tons of each individual type of GHG emissions expected from the Proposed Action and its alternatives. However, this EIS does analyze the two fundamental considerations required by current and former iterations of CEQ climate change guidance: (1) the potential effects of a proposed action on climate change, including both GHG emissions and reductions from the proposed action (see below), and (2) the effects of climate change on the proposed action and its environmental impacts.
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	59	<p>Estimated Emissions Speciated by Gas</p> <p>The SDEIS presents estimates in CO2e and not speciated by gas (CO2, CH4 and N2O). To ensure transparency of the analysis, EPA recommends presenting emissions estimates individually by GHG, as well as aggregated in terms of total CO2e in the FEIS.</p> <p>Additionally, the DSEIS indicates that approximately 99.9 percent of all processing GHG emissions are CO2. Similarly, construction, mining and commuting CO2 emissions comprise approximately 99 percent of the total GHG emissions from those activities.⁵⁸ EPA recommends the FEIS include data to support this statement. Specifically, EPA recommends providing data showing the amount of each GHG emitted from each emission source (i.e., the activities included in Tables 4.4-2a and 4.4-2b).</p>	CLI	The speciation of CO2e estimates has been incorporated into the Climate Change Specialist Report.
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	60	<p>Direct and Indirect GHG Emissions</p> <p>EPA recommends including a data table in the FEIS to support the DSEIS statement that the direct and indirect GHG emissions are only a small increase over the current regional GHG emissions. Much of the information to develop this table is already in the SEIS, but it is found in various sections and with differing units (e.g., MMT CO2 (e) vs. tons CO2 (e)). As an example, to produce a table to support this statement, Tables 4.4-2a and 4.4-2b could be augmented to include the estimated indirect emissions and the current Idaho GHG emissions inventory.</p>	CLI	A comparison table has been added to the EIS.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	61	<p>Access Road Alternatives</p> <p>The DSEIS indicates that the magnitude of the GHG emissions difference between the access road alternatives will be small compared to total SGP construction emissions during the construction phase. EPA recommends the FEIS support this statement with data demonstrating that the Johnson Creek Alternative has similar GHG emissions to the 2021 MMP Alternative. Preferably, the emissions data for this alternative would be presented the same as it is in Tables 4.4-2a and 4.4-2b so that the alternatives can be meaningfully compared.</p>	CLI	An estimate of the incremental difference between access route vehicle emissions has been added. Emissions associated with vehicle traffic represent approximately two percent of the total estimated GHG emissions from the Project. While a quantitative estimate has been included, it represents a small difference between the alternatives, within the margin of error for GHG emission estimates.
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	62	<p>Integration of Climate Science</p> <p>Flow (quantity and timing), summer air temperatures, and snowpack are likely to be substantially different over the span of this project (i.e., the next 15 to 20 years or longer) due to climate change. Further, conditions from that point in time into the future will be even further from estimates that are based on past conditions. It does not appear that climate change related concepts/forecasting/modeling are incorporated in the relevant sections of the DSEIS beyond the acknowledgement that climate change presents uncertainty.⁶¹ For example, the DSEIS indicates the 100-year flood recurrence interval has been the standard approach in culvert sizing, but it is now important to state future projections of high flow magnitude to conservatively account for climate change; and that modeled flow future conditions are based on historic condition.</p> <p>For the FEIS, EPA recommends incorporating state-of-the-climate science forecasting/modeling to estimate local climate conditions for proposed work that uses estimates of flow, air temperature, and snowpack. Examples of activities that would benefit from sophisticated forecasting would be road crossings design, stream reconstruction, and growth of riparian vegetation for stream temperature attainment. If site specific models and data are not available, consider incorporating climate science literature/information to inform and adjust existing models to conservatively adjust for climate change. Consider climate science projections (knowledge from the literature, forecasting/modeling) in aspects for both ongoing and postmining operations.</p>	CLI	The commenter requests incorporating state-of-the-climate science forecasting/modeling to estimate climate conditions for proposed work that uses estimates of flow, air temperature, and snowpack, if site-specific models and data are available, or to otherwise use climate science literature/information. The climate change literature and information are incorporated into the SDEIS on pages 3-64 - 3-66, where potential impacts to air temperatures and precipitation changes are discussed under the RCP 8.5 scenario. Discussion on other water-related changes, such as river-related flood risk, snowpack, and groundwater are also discussed. More specific information on projected stream temperatures can be found on pages 44 & 107 of the Fisheries and Aquatic Habitat Specialist Report. Additionally, the comment suggests updating the 100-year return interval flood interval to account for climate change. There are no known local models that downscale climate models into hydrological models for prediction, with instead observational detection of trends used to account for climate change impacts. A comprehensive evaluation of flood status and trends has been performed for this area using the flood potential method – these results indicate that floods in this area are generally relatively small, not flashy, and consistent, with trends indicating that floods are becoming more flashy, less frequent, but larger in magnitude for larger-scale floods (>4 year return interval), including the 100-year event. Considering this, Q100 design flood discharges would be increased by 6.4% from base values for all structures being designed at the SGP. The 6.4% increase is based on a hydrologic review conducted by USFS personnel.
Pam Wissenbach	19213	2	My first question is why was climate change not considered in the modeling and the predictions of water temperatures? I especially have big concerns about a rain on snow event. This is a very possible event that could have disastrous results. The hazards to four endangered fish species of increased water temperatures are huge. Climate change must be accounted for in predictions of the impacts Stibnite Mine will have on this area.	CLI	Climate change and predictions for water temperatures are discussed on pages 3-64 – 3-66 of the SDEIS. Potential impacts to air temperatures and precipitation changes are discussed under the RCP 8.5 scenario, along with other water-related changes, such as river-related flood risk, snowpack, and groundwater are also discussed. Specific information on projected stream temperatures can be found in the Fisheries and Aquatic Habitat Specialist Report. It should also be noted that the site water balance accounts for rain on snow events which is used to influence future conditions for the site.
Zack Waterman (Northern Rockies Conservation Director)	19317	4	The SDEIS also notably fails to consider climate change within modeling projections.	CLI	Climate change and climate change within modeling projections are discussed in Section 4.4 (Affected Environment—Climate Change), and extensively in the Climate Change Specialist Report.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	85	"Same as 2021 MMP, except the severity of climate change impacts may be reduced for surface water (quality and quantity), wetlands and riparian resources, vegetation (including general vegetation communities, botanical resources, and non-native plants), fish resources and fish habitat, wildlife and wildlife habitat, and special designations. " The "small incremental differences" noted above in this chapter will not result in these impacts. The effects on all the alternatives considered in detail should be exactly the same for this row.	CLI	The language was removed except for "Same as 2021 MMP."
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	631	"Climate Change " Please define the CEA here as it is in Table 5.1-1	CLI	The definition was added.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	182	"Climate change trends are discussed below by resource. " - Recommend this introductory statement be applied more consistently in the consideration of each resource in this section, and avoid venturing into impact analysis.	CLI	Noted, the various subsections are reviewed and adjusted where appropriate.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	183	"Climate Change Area of Analysis " - Recommend that this include a temporal scope stated also, so that people understand the long-term nature of the speculation of the climate trend.	CLI	The temporal scope was added to the Final EIS.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	184	"During 2020, approximately 127,214 hectares (314,352 acres) were burned from forest fires (NICC 2021) ." - Please clarify if this value relates to Idaho exclusively, or the entire US.	CLI	This is specific to Idaho. This clarification was added to the Final EIS.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	185	Statements such as "Although climate change would not impact the likelihood of a spill, it could potentially impact the severity of a spill " speak to impact analysis rather than a description of affected environment and do not seem appropriate in Section 3. Recommend removing from this section.	CLI	The portion of this section that outlines potential impacts has been removed.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	186	"The tribes have specific rights to the affected land ..." - It would be more accurate to state that the tribes have rights "regarding" the affected land rather than "to" the affected land.	CLI	This edit has been made to the Final EIS.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	187	"The SGP activities could contribute to factors that influence climate change. " Please reconcile this statement with the following statement in Section 3.4, and how "contribution to factors that influence climate change" will be considered within the context of the Forest Service 2009a which states that: "It is not currently feasible to quantify the indirect effects of individual or multiple projects on global climate change; therefore, determining significant effects of those projects or project alternatives on global climate change cannot be made at any scale."	CLI	The language referenced in USFS 2009a states that the effects could not be reasonably determined on a global scale. The "Issue" outlined in Section 4.4.1 indicates that the Project could contribute to climate change. Further in Section 4.4.1 it states that GHG emissions from the Project would be quantified and could impact resources, but not necessarily the potential impacts on a global scale. Because of this, no changes have been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	188	Recommend that this passage refer the reader to applicable SDEIS sections related to air quality analysis to provide a clearer picture of project emissions, which are only briefly described here and are not comprehensive.	CLI	A reference to Section 4.4.2.2 was added to send the reader to the actual Project GHG emissions.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	189	Recommend that the purpose of providing the emissions factors listed in Table 4.4-1 be clarified in the context of the analysis that is being conducted. Please clarify the analysis, how these emission factors play into it, and how is this information is considered in the rest of this section.	CLI	The clarification has been added to the Final EIS.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	190	"Under the No Action Alternative, the analysis area would continue to be impacted by current climate change trends. The No Action Alternative represents the baseline condition against which potential GHG emission and climate change effects are evaluated for the analysis area." - The text below does not address climate change characterizations for the No Action Alternative for resource areas that they characterize as being cumulative affected by climate change. Please include some characterization of continued impact by current climate change trends for the analysis area.	CLI	Language referring the reader back to Section 3.4.4.2 is added stating that the climate change trends described would be consistent with the No Action Alternative. Also, "unreclaimed" land language was added to describe potential climate change improvements over time.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	191	"Mineral exploration would continue to occur as part of the Golden Meadows Exploration Project, ... " Here and elsewhere, continued exploration is presented as a foregone conclusion for the No Action Alternative. It is not. Please replace 'would' with 'could'.	CLI	This revision has been made to the Final EIS.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	192	"While it is possible that processing may differ similar to mine operations, LOM 4 through LOM 18 are assumed to be identical to the maximum year ." - Recommend clarifying that this is a conservative assumption embedded in the emissions inventory and modeling. Thus it should be identified as such and should provide context for the over- estimation of actual emissions.	CLI	This clarification has been made in the Final EIS.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	193	"Therefore, meaningful connection of the 2021 MMP GHG emissions to climate change effects at the state, regional, or global level cannot be provided. " However, they could be presented as a percentage of these global/state/regional emissions, to provide context for the reader. This comparison to state emissions is done elsewhere in the SDEIS.	CLI	This clarification has been made in the Final EIS.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	194	Recommend adding a footnote indicating that, to embed conservatism in the emissions inventory and air modeling, emissions estimates for several ore processing and refining emissions activities are assumed to be constant based on the equipment design capacity; their actual emissions would be lower in Yrs 17 and 18 in particular.	CLI	This clarification has been made in the Final EIS.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	195	Recommend removing this entire paragraph as it includes speculative and inaccurate content. The nature of refinement that would be applied to the antimony concentrate, its inappropriately assigned similarity to gold refining, and assuming IPCO's CO2 emission rate for that refinement are all highly speculative and result in a GHG emissions value that is not reliable.	CLI	The paragraph has been retained but modified to account for a range of Lifecycle Assessments (LCAs) associated with potential GHG emissions from off-site processing options. See also the response to comment 17634.342.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	196	"Changes in landcover and slope stability due to climate change could create conditions that cause more frequent landslides, damaging vegetation and other forest resources. Landslides also could potentially impact surface water resources through increased sedimentation and runoff" - Recommend removing this passage as it is speculative, unsupported, and does not consider the potential variable of less winter precipitation.	CLI	The content is appropriate and was retained.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	197	"Much of this soil is currently poor quality (for example, old tailings piles), ..." - Please remove the reference to tailings as being considered as soil. In the context of the passage it suggests we plan to incorporate them into soil for reclamation activities which is inaccurate.	CLI	This revision has been made to the Final EIS.

Resources Idaho, Inc.)					
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	198	<i>Regional climate change could affect the ability of Operations Area Boundary streams to maintain previous flow rates and recharge of water supply due to changes in Idaho snowpack and precipitation patterns (Halofsky et al. 2018).</i> " - Use of this citation here is inappropriate as Halofsky et al 2018 did not address the SGP.	CLI	This revision has been made to the Final EIS. Note that this is a general statement for Idaho, no specifics for the Project.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	199	<i>"Climate change induced changes in precipitation and evaporation could also impact the overall site-wide water balance which could result in significant changes to the amount of water being treated and discharged.</i> " - Please remove or edit this passage as appropriate; it disregards the climate sensitivity analysis that was applied to the Site Wide Water Balance.	CLI	This revision has been made to the Final EIS.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	200	<i>"...more vegetation in the SGP area could be lost, creating greater visibility of the SGP and associated impacts to scenic resources.</i> " - Please remove or revise this statement as appropriate; it does not recognize the limited area from which the SGP is visible, regardless of a reduction in vegetation.	CLI	This revision has been made to the Final EIS. The limited view of the SGP is irrelevant to the viewsheds that could be impacted. Therefore, the change was not made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	201	<i>"The Johnson Creek Route Alternative would have the effect of decreasing overall construction phase GHG emissions; however, the construction activities to complete major improvements on the Johnson Creek Route would likely offset the decrease and would likely end up very similar to the 2021 MMP ."</i> - Recommend clarifying this sentence to avoid perceived contradiction.	CLI	This revision has been made to the Final EIS.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	202	<i>"...the severity of impacts to wetlands and riparian resources would be less for the Johnson Creek Route Alternative compared to the Burntlog Route "</i> - Recommend removing as this is not a comment on climate change.	CLI	The suggested revision was not made as it provides context between the two alternatives.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	203	<i>"The Burntlog Route would not be constructed under the Johnson Creek Route Alternative, avoiding the construction of approximately 20 miles of new roadway. Although the impacts of climate change would be the same as 2021 MMP, it is expected that not constructing the Burntlog Route would help to reduce the severity of impacts to proposed-threatened plant species (whitebark pine), federally listed fish species, wildlife and wildlife habitat, and IRA s."</i> - recommend removing as this is not a comment and climate change and should not be here.	CLI	The suggested revision was not made as it provides context between the two alternatives.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	204	<i>"However, existing and approved activities (i.e., approved exploration activities and associated reclamation obligations) would continue ..."</i> - Approved exploration activities 'could' continue, but are not guaranteed. Please change 'would' to 'could' throughout this document.	CLI	This revision has been made to the Final EIS.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	205	<i>(Knowles and Gumtow 1996).</i> - Recommend an alternative citation. The referenced document is not a scientific study, which makes this statement weakly supported, even though the bull trout is very cold-water adapted.	CLI	Citation has been updated to USFWS 2015.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Resources Idaho, Inc.)					
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	206	"Mineral exploration would continue to occur as part of the Golden Meadows Exploration Project." - Approved exploration activities 'could' continue, but are not guaranteed. Please change 'would' to 'could' throughout this document.	CLI	This revision has been made to the Final EIS.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	207	"There is very little information on the energy usage, and GHG emissions, of smelting and refining antimony concentrate..." - Recommend removing this entire paragraph as it includes speculative content. The nature of refinement that would be applied to the antimony concentrate, its assumed similarity to gold refining, and assuming IPCO's CO2 emission rate for that refinement are all highly speculative and result in a GHG emissions value that is not reliable.	CLI	This paragraph was not removed but has been updated for clarity and discussion of potentially variability has been added. See also the response to comment 17634.342.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	208	"...however, increased particulate matter and other criteria pollutants as a result of climate change (e.g., potential for increased wildfires and decreased groundcover resulting in more particulates in the air) could persist within the SGP area (Jacob and Winner 2009)." - Recommend a more applicable reference be included here: the cited document is not applicable to assessing particulate matter at the SGP as it predates the project.	CLI	The reference is appropriate; however, explicit discussion of the SGP has been removed.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	209	"Much of this soil is currently poor quality (for example, old tailings piles), and would be unlikely to naturally revegetate at a normal rate" - Recommend clarifying this statement, which appears to suggest that legacy tailings will be incorporated into soils used for reclamation. This is not accurate.	CLI	The reference to old tailings piles has been removed.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	210	"Climate change induced changes in precipitation and evaporation could also impact the overall site-wide water balance which could result in significant changes to the amount of water being treated and discharged." - This passage should discuss the climate sensitivity analysis on the Site Wide Water Balance that was conducted at the request of the USFS and Stantec.	CLI	This revision has been made to the Final EIS.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	211	"Changing climatic conditions are expected to exacerbate the damage and loss of cultural resources and natural areas utilized by tribes for activities such as hunting, fishing, and gathering in the SGP area through increased soil erosion, more frequent and intense wildfires, flooding, degraded water quality, and wildlife and fish habitat impacts." - It is unclear whether this statement speaks to background effects of climate change or project-specific effects. If the latter, this passage should better characterize both negative and positive impacts to the indicated resources.	CLI	The referenced statement pertains only to effects of changing climate conditions on these resources. The Project-specific positive and negative effects pertaining to proposed activities are discussed in the other resource sections of the EIS.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	212	"The Johnson Creek Route Alternative would have the effect of decreasing overall construction phase GHG emissions;" - Recommend clarifying that this alternative requires 2 additional years of construction, which would generate additional GHG emissions for additional layback work, (including temporary road installation and drilling), and installation of retaining walls, not to mention limited workdays resulting in additional employee travel to and from the work site.	CLI	The additional descriptive information associated with the alternative has been added to the Final EIS.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	213	"This approach is done for ease of permitting". Recommend adding that this approach to developing emissions inventories embeds conservatism into the emissions inventory and resultant modeling and is not necessarily done for "ease of permitting".	CLI	This revision has been made to the Final EIS.

Resources Idaho, Inc.)					
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	214	<i>"Ongoing mining activities on patented land Mineral exploration and mining have occurred in several locations around the SGP area.</i> <i>Exploration activities are ongoing for potential future mining development ."</i> - Please clarify what these activities are and where they are occurring consistent with the examples provided for the other project types included here.	CLI	The ongoing and reasonably foreseeable exploration and mining activities are listed in the cumulative effects description in Chapter 5 of the EIS.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	215	<i>"Direct and indirect GHG emissions and their associated impacts would be the same under the Johnson Creek Route Alternative as those discussed under the 2021 MMP."</i> - Recommend clarifying that this alternative requires 2 additional years of construction, which would generate additional GHG emissions for additional layback work, (including temporary road installation and drilling), and installation of retaining walls, not to mention limited workdays resulting in additional employee travel to and from the work site.	CLI	This recommended additional information was added in response to comment 19325.212. It was not explicitly added again here.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	216	<i>"Exploration activities associated with the Golden Meadows Exploration Project would continue..."</i> - Continued exploration is not guaranteed. Please replace "would" with "could".	CLI	This revision has been made to the Final EIS.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	7	Comments are provided for Sections 3.4, 4.4, and the Climate Change Specialist Report. The challenge in assessing this resource is inherent in the Forest Service guidance, which states: "It is not currently feasible to quantify the indirect effects of individual or multiple projects on global climate change; therefore, determining significant effects of those projects or project alternatives on global climate change cannot be made at any scale" (Section 3.4.3). Thus, the USFS is bound to inform its decision-making process "...qualitatively describing the type and extent of potential climate change impacts on the physical, social, and biological resources in the analysis area since information is not available to address such effects with quantitative certainty" (Section 4.4.1). Therefore, to support the USFS analysis, our comments focus on technical clarifications to the descriptions of the alternatives.	CLI	Comment noted. No response required.
Jon Robison	19330	11	The fact that the document fails to account for Climate Change is unacceptable, as climate change will likely exacerbate many of the negative effects of the project. Models exist that the Forest Service can use to disclose these risks.	CLI	Potential impacts and effects of climate change on the Project and potential effects of the Project are addressed throughout the EIS and Climate Change Specialist Report in a qualitative manner. Additionally, Project-related GHG emissions are outlined.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	341	T. Climate Change In addition to the comments below, the Forest Service must incorporate CEQ's recent interim guidance to assist federal agencies in analyzing greenhouse gas emissions and climate change effects of their proposed actions under NEPA. As CEQ poignantly reminds all federal agencies: The United States faces a profound climate crisis and there is little time left to avoid a dangerous—potentially catastrophic—climate trajectory. Climate change is a fundamental environmental issue, and its effects on the human environment fall squarely within NEPA's purview. Major Federal actions may result in substantial GHG emissions or emissions reductions, so Federal leadership that is informed by sound analysis is crucial to addressing the climate crisis. Federal proposals may also be affected by climate change, so they should be designed in consideration of resilience and adaptation to a changing climate. Climate change is a particularly complex challenge given its global nature and the inherent interrelationships among its sources and effects. Further, climate change raises environmental justice concerns because it will disproportionately and adversely affect human health and the environment in some communities, including communities of color, low-income communities, and Tribal Nations and Indigenous communities. Given the urgency of the climate crisis and NEPA's important role in providing critical information to decision makers and the public, NEPA reviews should quantify proposed actions' GHG emissions, place GHG emissions in appropriate context and disclose relevant	CLI	On January 9, 2023, the Council on Environmental Quality (CEQ) published interim "National Environmental Policy Act Guidance on Consideration of Greenhouse Gas Emissions and Climate Change" in the Federal Register (CEQ 2023). CEQ grants agencies the discretion to decide whether to apply the guidance to NEPA analyses that were in progress when the guidance was issued. The interim CEQ guidance was published late in the development process for the DSEIS, and therefore this EIS primarily relies on earlier CEQ guidance on considering climate change in NEPA (CEQ 2016). For example, this EIS does not include all new recommendations such as applying social cost of GHG estimates to the incremental metric tons of each individual type of GHG emissions expected from the Proposed Action and its alternatives. However, this EIS does analyze the two fundamental considerations required by current and former iterations of CEQ climate change guidance: (1) the potential effects of a proposed action on climate change, including both GHG emissions and reductions from the proposed action (see below), and (2) the effects of climate change on the proposed action and its environmental impacts. Currently, potential climate change impacts are addressed throughout the EIS and Specialist Report in a qualitative manner. Additionally, Project-related GHG emissions are outlined.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>GHG emissions and relevant climate impacts, and identify alternatives and mitigation measures to avoid or reduce GHG emissions. CEQ encourages agencies to mitigate GHG emissions associated with their proposed actions to the greatest extent possible, consistent with national, science-based GHG reduction policies established to avoid the worst impacts of climate change.</p> <p>The Forest Service has obligated itself to comply with the Council on Environmental Quality (CEQ) regulations for implementing the procedural provisions of NEPA. 36 C.F.R. 220.1(a). Thus, when analyzing the SGP the agency should consider “(1) the potential effects of a proposed action on climate change, including by assessing both GHG emissions and reductions from the proposed action; and (2) the effects of climate change on a proposed action and its environmental impacts.” In addition to quantifying all of a proposed action’s projected GHG emissions or reductions for the expected lifetime of the action, CEQ recommends that agencies also “use the best available social cost of GHG estimates to translate climate impacts into the more accessible metric of dollars” thus allowing “decision makers and the public to make comparisons, help evaluate the significance of an action’s climate change effects, and better understand the tradeoffs associated with an action and its alternatives.” As explained below, the SDEIS completely fails to follow any of CEQ’s recommendations. Not analyzing these highly relevant aspects of the SGP fails to disclose vital information that the public and the decision maker need to ensure informed decision making.</p>		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	342	<p>1. The SDEIS fails to provide a comprehensive estimate of greenhouse gas (GHG) emissions for the proposed Stibnite Gold Project</p> <p>The GHG emissions calculation is based on a mine life of 20 years, (p. 4-63), yet the SDEIS (p. 2-8) predicts that long-term water treatment will be required at SGP (mine year 16 through 40), Estimated emissions from these additional activities should be included in the calculation. The Reclamation and Closure Plan indicates that large volumes of compost will be transported to the mine from southeast Idaho for reclamation efforts. The transport of compost and other soil amendments should also be included in the calculations.</p> <p>The SDEIS (p. 4-67) relies on estimates of GHG emissions for antimony refining, based on gold processing using electrolytic refining methods. However, most antimony sulfide concentrates are refined with pyrometallurgy smelting, relying on volatilization roasting in rotary kilns—reduction smelting, which uses much larger amounts of energy. If reduction smelting is anticipated, EISS (2022) estimates the total refining emissions at 24,300-24,600 metric tons CO₂ eq. This is substantially larger than the estimated 4,055 MT in the SDEIS. Perpetua should disclose the expected refining method for the antimony sulfide concentrate, and the SDEIS should include GHG emissions relative to that processing method. The SDEIS also fails to quantify the estimated GHG emissions for transporting antimony concentrate off-site for processing. The SDEIS (p. 4-66, 4-67) states that “Because it is unknown at this time where the concentrate from the mine would be processed, total GHG estimations associated with the transport of antimony concentrate would be speculative.” However, there are reasonable assumptions that can be made about potential off-site processing facilities for antimony concentrate, and therefore a reasonable range of GHG emissions estimates can be calculated. Perpetua states in its materials that, “The concentrate, when sold, would likely be shipped to facilities outside of the United States for smelting and refining because there are currently no such facilities operating in the United States with capacity for refining antimony sulfide concentrate.” Perpetua should be required to provide a short list of off-site processing options for antimony to demonstrate that it can, as it claims, produce antimony for marketable use. This information is reasonably available, and should be used to estimate emissions in the SDEIS.</p> <p>(TABLE)</p>	CLI	<p>Section 4.4.2.2 provides an estimate for off-site antimony processing based on the assumptions referenced therein. Different processing options under different assumptions would result in changes in emissions estimates up to 67,000 metric tons CO₂e based on Lifecycle Assessment of shipping and processing antimony at overseas processing plants.</p> <p>Vehicle transportation accounts for a relatively small component of overall Project GHG estimates (i.e., two percent). Incremental changes in the number and nature of shipments to the Project over its lifespan are within the estimation error of GHG emissions.</p>
Bonnie Gestring (Northwest Program Director,	17634	343	<p>Based on an analysis of potential refining sites, ore grade, likely transport methods, and other factors, EISS (2022) completed a rough estimate of the total global warming potential (GWP) for antimony transport and refining from the SGP to two options: the USAMSA refinery in Mexico and the SPMP refinery in Oman. The analysis (outlined above in Table 4) estimates an additional 30,794 metric tons</p>	CLI	See the response to comment 17634.342.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Earthworks) and seven others			CO2eq for transport and processing in Mexico and 66,708 metric tons of CO2eq for Oman – a substantial increase in total emissions associated with processing antimony from SGP.		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	344	2. The SDEIS fails to take a hard look at the GHG emissions in the proposed alternative According to the SDEIS, direct and indirect GHG emissions and their associated impacts would be the same under the Johnson Creek Route Alternative as those discussed under the 2021 MMP. (ES-10) The SDEIS says that the Johnson Creek Route Alternative would have the effect of decreasing overall construction phase GHG emissions; however, the construction activities to complete major improvements on the Johnson Creek Route would likely offset the decrease and would likely end up very similar to the 2021 MMP. (p. 4-72) However, the SDEIS provides no GHG emissions analysis to support this comparison. The SDEIS should calculate the GHG emissions for the 2021 MMP and the alternative, and provide an accurate comparison.	CLI	An estimate of the incremental difference between access route vehicle emissions has been added. Emissions associated with vehicle traffic represent approximately two percent of the total estimated GHG emissions from the Project. While a quantitative estimate has been included, it represents a small difference between the alternatives, within the margin of error for GHG emission estimates.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	345	3. The SDEIS comes to unsupported conclusions about regional GHG emissions The SDEIS downplays the potential regional increase in emissions from the SGP project by comparing the GHG emissions from the SGP project with all other emissions in the State of Idaho. According to the SDEIS (p. 4-63), “GHG emission inventory for the State of Idaho (represents a basis for comparison with action alternative GHG emission estimates).” It also finds that “Overall, the SGP direct and indirect GHG emissions would be a negligible and long-term increase in regional GHG emissions,” and the “Effects of ongoing climate change in the SGP area following implementation of the 2021 MMP would be largely the same as those that would occur regionally and in Idaho without the SGP.” (SDEIS, p. 4-67) emphasis added. Yet, the SDEIS has not compared the SGP emissions with other regional emissions. It has only compared the SGP emissions with those of the entire state. CEQ guidance to federal agencies directly discourages this type of approach, saying “CEQ recognizes that the totality of climate change impacts is not attributable to any single action, but are exacerbated by a series of actions including actions taken pursuant to decisions of the Federal Government. Therefore, a statement that emissions from a proposed Federal action represent only a small fraction of global emissions is essentially a statement about the nature of the climate change challenge, and is not an appropriate basis for deciding whether or to what extent to consider climate change impacts under NEPA.” Similarly, comparing SGP emissions to that of the entire state of Idaho is inappropriate. The SDEIS must provide an accurate and reasonable assessment of the regional contributions of the proposed project by considering SGP’s projected GHG emissions with regional emissions.	CLI	The worst case GHG emission year during the life of the mine was evaluated along with the EPA equivalency calculator to provide perspective of the direct GHG emissions. Also, a brief discussion about county GHG emissions was added to the Final EIS.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	346	4. The SDEIS must take a hard look at the potential impacts to mine infrastructure related to the effects of climate change, and the potential environmental consequences. There are an increasing number of reports from industry, regulatory agencies, and academia that identify the increased risks of climate change to the mining industry and the need to incorporate climate change predictions into mine plans and practices. Recent experience shows that abnormally high levels of precipitation can destroy waste dumps, seepage capture systems, and mine access roads; cause impoundments to overflow and dams to be breached; and push water treatment costs over budget or cause releases of untreated water. A recent report from the World Meteorological Organization has found that climate and weather related disasters have surged five-fold over the last 50 years. According to a technical presentation by a BLM geologist, who points to the failure of a seepage capture system that was designed for a 100-year, 24-hour storm event at the Zortman Landusky cyanide leach gold mine in Montana: “The reality is the industry is making closure, reclamation and drainage treatment predictions based on a historic climate that no longer exists.” These impacts underscore the need to analyze and plan for climate change throughout a project’s design, construction, operation and closure. For example, a 500-year storm event at the Stillwater Mine in Montana in June 2022, resulted in severe damage to the access road, preventing access to the site for a number of weeks and causing severe erosion along the road. (See photo from Billings Gazette of mine and access road). The SDEIS should also include an emergency plan in the event of evacuation or damage from wildfires, as recently occurred at the Donlin Gold Mine in Alaska. The SDEIS must analyze the potential impacts of climate change, including more frequent and severe storm events, including those that exceed the design parameters for mine infrastructure, such as stormwater management infrastructure, resulting in more frequent untreated releases and potentially	CLI	The effect of climate change on proposed revegetation efforts and how this relates to soil quality is discussed in the SDEIS primarily on pages 4-68 – 4-69 and in the Climate Change Specialist Report on pages 33-35. The SDEIS notes that activities in the 2021 MMP would involve revegetating areas disturbed by historic mining, construction, and operation activities in the Operations Area Boundary. It notes that activities to improve and revegetate existing poor-quality soils could reduce climate-induced impacts to soils in the short-term by allowing the soil to retain more moisture during the summer; it also acknowledges that climate changes could potentially diminish soil quality over time and affect revegetation efforts in the long-term (SDEIS 4-68; Climate Change Specialist Report). The need to consider climate changes in revegetation is discussed in the SDEIS, which states that climate changes including changes in future weather patterns, precipitation amounts and seasonality, and resilience of species to fire and drought would be considered when identifying reclamation methods and goals (SDEIS 4-69). Potential climate change effects on erosion and on soil/reclamation cover materials are discussed in the SDEIS on pages 3-66 and 3-67, and erosion control best management practices are referenced throughout the document.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			degrading water quality. The SDEIS must also take a hard look at the potential impacts of climate change on revegetation efforts associated with proposed reclamation, and increased erosion from all mine facilities. The SDEIS comes to unsupported conclusions about climate change. According to the SDEIS (p. ES-10) "Closure and reclamation activities under the alternatives could reduce climate change impacts by improving soil quality and implementing best management practices during all phases of the SGP." Yet, the SDEIS proposes to authorize the use of soils with arsenic concentrations up to 3,000 ppm in root zone material used for reclamation, worsening metal concentrations in soil. There is no data or analysis to indicate that soil quality will be improved in such a way that it will reduce climate change impacts.		
Judy Anderson	17644	1	<p>I know you have suffered with this complex behemoth project. I know you have worked hard and probably had to compromise or ignore things when you did not want to. This is a small town and word gets around and I know you have been under intense political pressure and agency pressure. I am sorry.</p> <p>But I am going to have to put more pressure on you. And it is the pressure we all feel at this juncture watching with growing horror at the chaos unfolding as the result of climate change. Basically, humans, especially Americans, have refused to change and the result has been everything is changing.</p> <p>But the Forest Service, as trusted stewards of our land and waters and the creatures who inhabit them, has got to change. Whereas a few years ago it may have been excusable in an EIS to give climate change short shrift. It is unconscionable now. And especially unforgivable in an agency supposedly guided by science and dealing with a huge industrial gold mine like Stibnite.</p> <p>As Antonio Guterres, Secretary General of the United Nations said several months ago," We are on a highway to climate hell with our foot still on the accelerator.... Humanity has a choice-cooperate or perish." The sense of urgency about the timetable climate change is forcing on us, felt by much of the world and by many here in Valley County, is completely lacking in the DEIS and the SDEIS. Why? The greatest challenge of the 21st century is substantially ignored?</p> <p>The caveats in the SDEIS when it comes to the huge amount of GHG emissions that will be generated by the mine are unacceptable. It claims that the emissions don't really matter because there are no Idaho or Fed regulations so the SDEIS can't "quantify the costs or significance". Does that justify that the Forest Service is not going to analyze them or demand responsibility or mitigation for them? REALLY?</p>	CLI	On January 9, 2023, the Council on Environmental Quality (CEQ) published interim "National Environmental Policy Act Guidance on Consideration of Greenhouse Gas Emissions and Climate Change" in the Federal Register (CEQ 2023). CEQ grants agencies the discretion to decide whether to apply the guidance to NEPA analyses that were in progress when the guidance was issued. The interim CEQ guidance was published late in the development process for the SGP DSEIS, and therefore this EIS primarily relies on earlier CEQ guidance on considering climate change in NEPA (CEQ 2016). For example, this EIS does not include all new recommendations such as applying social cost of GHG estimates to the incremental metric tons of each individual type of GHG emissions expected from the Proposed Action and its alternatives. However, this EIS does analyze the two fundamental considerations required by current and former iterations of CEQ climate change guidance: (1) the potential effects of a proposed action on climate change, including both GHG emissions and reductions from the proposed action (see below), and (2) the effects of climate change on the proposed action and its environmental impacts.
Judy Anderson	17644	2	And then the SDEIS basically says that, "Aw,heck they aren't that big when you compare them to the whole state or the global emissions" Even though the Council on Environmental Quality makes it clear that Federal agencies cannot ignore impacts of climate change from proposed actions because the emissions only represent a small fraction of global emissions. In fact, they say that comparing emissions of any project to global emissions is a flawed understanding of how climate change works and cannot be used as a basis for deciding not to consider climate change impacts under NEPA.	CLI	On January 9, 2023, the Council on Environmental Quality (CEQ) published interim "National Environmental Policy Act Guidance on Consideration of Greenhouse Gas Emissions and Climate Change" in the Federal Register (CEQ 2023). CEQ grants agencies the discretion to decide whether to apply the guidance to NEPA analyses that were in progress when the guidance was issued. The interim CEQ guidance was published late in the development process for the SGP DSEIS, and therefore this EIS primarily relies on earlier CEQ guidance on considering climate change in NEPA (CEQ 2016). For example, this EIS does not include all new recommendations such as applying social cost of GHG estimates to the incremental metric tons of each individual type of GHG emissions expected from the Proposed Action and its alternatives. However, this EIS does analyze the two fundamental considerations required by current and former iterations of CEQ climate change guidance: (1) the potential effects of a proposed action on climate change, including both GHG emissions and reductions from the proposed action (see below), and (2) the effects of climate change on the proposed action and its environmental impacts.
Judy Anderson	17644	3	In addition, the calculations of the emissions from the proposed Stibnite mine are problematic as they leave out sectors. Table 4.4, 2a and 2b lists the tons per year but leaves out years 19 through 40. The SDEIS also leaves out emissions from: antimony concentrate transport to a processing plant; a more realistic estimate of emissions from the preferred method of reduction smelting of antimony; the emissions from transport or commuting from the junction of Warm Lake Road to wherever cars or trucks are going or coming from.	CLI	The activities described in Tables 4.4-2a and 4.4-2b would not continue past Year 18. The effects of vehicle travel, off-site power generation, and antimony concentrate are described in SDEIS Section 4.4.2.2 under the Indirect GHG Emissions section.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			And the SDEIS also leaves out the significant emissions from the massive use of electrical energy as 40% of Idaho Power's energy still comes from fossil fuels not hydro...and hydro is dependent on water flows which are and will be impacted by climate change. There would be an approximate annual emissions amount of 97,000tons of CO2e being added to our region's emissions from Perpetua's electrical use that does not currently exist and is not accounted for in the SDEIS. There is again no mitigation offered. Without an addition of new energy generation to the Idaho Power grid to mitigate the additional demand and mitigate the resulting emissions, the Perpetua increased demand and generated emissions would be the responsibility of Idaho power customers including the City of McCall and its residents to solve and pay for.		
Judy Anderson	17644	4	These unmitigated GHG emissions (those acknowledged in the SDEIS and some ignored) would approximate over the lifetime of the operations 4,992,546 Metric Tons of CO2e . The burden of these emissions, which could almost double what we are emitting now, will fall on the city and the county to address. This will frustrate our present efforts to curtail emissions and frankly is unfair and would be taking all of us in the opposite direction of where we should be going as a region and a society.	CLI	No further response required. General in nature or position statement. It is acknowledged and understood that concerns regarding potential long-term environmental impacts, ecological integrity, and the well-being of potentially affected communities are valid and important to consider. During the decision-making process, the Forest Service will seek to identify the best possible balance between environmental protection, community needs, and sustainable forest management.
Judy Anderson	17644	5	<p>The second horrifying issue involving climate change is the fact that most of the negative impacts of the mine (some of which are admitted in the SDEIS) will be exacerbated, accelerated, and intensified by climate change. (4-67 to 4-72 SDEIS)</p> <p>So whether we are talking about the stress on recharging groundwater; lower stream flows; the difficulty of revegetation and reclamation; high water temperatures; loss of wetlands and riparian areas; vulnerability to floods, landslides, avalanches; air pollution...ALL of these impacts will be exacerbated by climate change and are guaranteed to worsen thru time as climate change gets more chaotic. And any mitigation proposed for any impacts in this mine are completely called into question by the effects of climate change and their increasing extremeness and unpredictability.</p> <p>The SDEIS mentions this possibility but then drops it ...just drops it. There is no comprehensive climate mitigation plan offered. There are no buffers mentioned that could be built into any measurements or models to take into account the inevitable trajectory of climate change.... a trajectory that will affect every aspect of this project and will only intensify.</p> <p>Any mitigation proposed for any impacts in this mine are completely called into question by the effects of climate change and their increasing extremeness and unpredictability.</p>	CLI	On January 9, 2023, the Council on Environmental Quality (CEQ) published interim "National Environmental Policy Act Guidance on Consideration of Greenhouse Gas Emissions and Climate Change" in the Federal Register (CEQ 2023). CEQ grants agencies the discretion to decide whether to apply the guidance to NEPA analyses that were in progress when the guidance was issued. The interim CEQ guidance was published late in the development process for the SGP DSEIS, and therefore this EIS primarily relies on earlier CEQ guidance on considering climate change in NEPA (CEQ 2016). 					development process for the SGP DSEIS, and therefore this EIS primarily relies on earlier CEQ guidance on considering climate change in NEPA (CEQ 2016). For example, this EIS does not include all new recommendations such as applying social cost of GHG estimates to the incremental metric tons of each individual type of GHG emissions expected from the Proposed Action and its alternatives. However, this EIS does analyze the two fundamental considerations required by current and former iterations of CEQ climate change guidance: (1) the potential effects of a proposed action on climate change, including both GHG emissions and reductions from the proposed action (see below), and (2) the effects of climate change on the proposed action and its environmental impacts.
Samuel Penney (Chairman)	19396	24	<p>In Section 1-27 the proponent noted that EO 13990 (Protecting Public Health and the Environment and Restoring Science to Tackle the Climate Crisis) was revoked and that the Forest Service complies with the requirements of valid EOs when completing NEPA and implementing processes.</p> <p>However, they failed to mention E.O. 14008 (Climate Crisis: Tackling the Climate Crisis at Home and Abroad); or the Justice 40 initiative that both apply to this project. Mining is specifically mentioned in E.O. 14008, but not reviewed in this SDEIS. Also, E.O. 14008 required all federal agencies to prepare Climate Adaptation Plans. In the US Forest Service Climate Adaptation Plan, published in July 2022, a number of recommendations were put forth regarding extreme events, environmental justice, and disproportionate impacts to Tribal Nations that are relevant to the Stibnite SDEIS. Given that the proponent missed these climate change related policies, it is likely others were overlooked.</p>	CLI	Both EO 13990 and EO 14008 are outlined in Section 3.4.3. Further, Section 3.22.3 discusses EO 14008. The Climate Adaptation Plan was not included is incorporated in the Final EIS.
Samuel Penney (Chairman)	19396	43	<p>Table 2.4-13 Proponent Proposed Design Features</p> <p>Climate Change measures are listed in only two MMPs. Previous comments on this matter were not addressed, namely that using LED light bulbs and smart technology for efficiency is a woefully inadequate response to protect the climate. The EPA is in the midst of rulemaking regarding heavy trucks and off-road vehicles, which will go into effect during this project. Climate mitigation measures that could be deployed include things like installing electric vehicle charging stations, powering part of the operation with solar or waste heat, using energy efficient appliances and HVAC equipment, and off-setting emissions through carbon sequestration. Federal incentives and tax credits are now available to deploy clean energy technology and energy efficient infrastructure that lower the cost to transition to fossil free energy, but also reduce operation costs over the lifetime of buildings, vehicles, etc. and increase profitability and shareholder satisfaction, but these measures were not included.</p>	CLI	The suggestions were reviewed. While these options are feasible, they are not an absolute requirement. Therefore, these are not be mandated by the EIS.
Samuel Penney (Chairman)	19396	44	<p>Table 2.8-1 Alternative Comparison and Impact Summary</p> <p>Table states that SGP activities could contribute to factors that influence climate change, and then lists “Maximum LOM 3 200,671 MT (221,201 short tons/yr.) of CO 2e of total annual GHG emissions.” This should be changed to “will contribute an estimated x tons/year of GHG emissions” because ALL GHG emissions affect the climate. Mitigation measures that reduce the amount of annual and cumulative GHG emissions could be proposed per the previous comment. In addition, measures could be proposed to sequester carbon and off-set the GHG emissions produced by this project.</p>	CLI	The revision has been made in the Final EIS.
Samuel Penney (Chairman)	19396	75	<p>3.4 Climate Change</p> <p>Best Science is required for evaluating a project’s likely environmental consequences. The climate analysis relied heavily on the International Panel on Climate Change (“IPCC”) Sixth Assessment and excluded Idaho specific climate literature. It also did not include the IPCC 1.5 Report which explains why limiting global temperature rise to 1.5 °C is necessary to avoid the worst risks associated with climate change and the timeline for which this must be accomplished. The proponent also notes that the Higher greenhouse gas (“GHG”) emissions from this Project add a small proportion to total emissions, skirting the problem that all emissions must be dramatically reduced to avoid the worst effects of climate change. Pleune et al. (2020) expressed this as follows:</p> <p>The hotter the world gets, the graver the forecasted consequences. Observed warming trends reinforce the importance of limiting global warming to 1.5°C to</p>	CLI	Comment noted. The IPCC assessment includes the most up-to-date science. Target dates are encouraged, but not an absolute requirement.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>avoid catastrophic effects and reduce the severity of unavoidable changes. To achieve this result, the International Panel on Climate Change (“IPCC”) identifies a reduction target for global net anthropogenic carbon emissions of 45 percent by 2030 and a net zero target by 2050 in order to limit warming to a (hopefully) manageable level. At this late stage in the game, the equation is simple. Higher greenhouse gas (“GHG”) emission trajectories lead to higher forecasted global warming with graver environmental and security consequences. In other words, high emissions result in high risk. Failing to reduce GHG emissions is a risk management failure.</p> <p>Again, emissions must be cut by 45% by 2030, and reach net zero by 2050 to limit the rise in global temperature to 1.5 °C. Gold mining is an energy intensive industry that contributes to greenhouse gas emissions. The proposed mitigation measures do not reflect the urgent need to cut emissions from building operation, industrial processes, or transportation. In addition, the omission of information from the IPCC 1.5 report provides an incomplete summary of the risks of climate change or the urgency of a rapid response to the climate crisis.</p>		
Samuel Penney (Chairman)	19396	76	<p>Though the federal government may not currently have standards in place to limit emissions from mines, new buildings, and heavy duty trucks, the EPA is in the midst of rulemaking for heavy duty vehicles, and proposed rules were released in March 2022. The Securities and Exchange Commission has also released proposed rules. As climate impacts intensify, more policy, regulations, legal scholarship, and legal actions can be expected to try to prevent the worst impacts of climate change, and to hold those who fail to do so to account. Climate change is an existential threat to humanity’s existence, creates tremendous risks including the displacement of human beings and wildlife, extinction of 30-50% of animal and plant species by 2050, and 90% of marine species by 2100. It also is a risk to the economy and a serious risk to mining operations. As the planet gets warmer, the potential to trigger tipping points that lead “to significant, policy relevant impacts, including substantial sea level rise from collapsing ice sheets, dieback of biodiverse biomes such as the Amazon rainforest or warm-water corals, and carbon release from thawing permafrost.” In light of the risk, it behooves us all to incorporate mitigation measures into projects that reflect the urgency of the climate crisis, and that address the cumulative need for actions across all sectors and projects, regardless of proportional individual contributions to the problem. In addition, the Inflation Reduction Act has committed millions of dollars in incentives for electrification and adoption of electric vehicles including heavy duty trucks. Though it may not currently be required, it is something that would be truly green and a clear example of a commitment to the environment and the climate, which the proponent purports to care about. It also behooves us all to prioritize where our money, time, and resources are spent in the next ten years. Given that antimony is a critical mineral used in batteries, the benefit may outweigh the cost of this mine for its use in batteries, but only if the contribution of the mine to greenhouse gasses are off-set during operations, not in 23 years. Indeed, with risks so grave, one might argue that the US Forest Service “has a statutory duty to respond to climate change, which includes the duty to avoid exacerbating climate change” as Pleune et al. argue so persuasively regarding the BLM and oil and gas leasing.</p>	CLI	Comment noted. No response required.

Soils and Reclamation Cover Materials

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Daniel S. Kline	16484	2	<p>Soils and Reclamation Cover Materials</p> <p>Total Soil Resource Commitment (TSRC) as defined in the Payette Forest Plan (Forest Service 2003a) and Boise Forest Plan (Forest Service 2010a), is the conversion of a productive site to an essentially non-productive site for a period of more than 50 years¹. Regarding soil productivity the SDEIS makes the following statement.</p> <p><i>“As a rule, the processes responsible for restoration of soil productivity occur over a very long timeframe (centuries to millennia) and do not directly correlate to successful reclamation, which is mainly oriented to short-term objectives. The short timeframe for achievable reclamation measures (e.g., 5 to 10 years) would not be sufficient to establish trends in soil resources and productivity that would take many centuries to millennia to develop within the conditions that pertain to the activity area, especially with respect to the short growing season and harsh winters. Important measures of long-term soil productivity would include: development of a litter layer, biotic crust and/or A horizon (organic matter-enriched surface layer); development of soil structure to support water and air movement; physical and chemical weathering of coarse fragments to add soil fines and nutrients; and development of the soil food web, nutrient cycles, and microbial community, especially the mycorrhizal network. Thus, the recovery of greater than 40 percent soil productivity within a 50-year timeframe is unlikely (Forest Service 2022c).²”</i></p> <p><i>“To conservatively address uncertainty in reclamation success, this analysis of TSRC assumes that all SGP-related disturbances in the PNF activity area would be considered TSRC due to the site-specific challenges and the duration and nature of soil disturbance to support the mining activities.²”</i></p> <p><i>“...recovery of soil productivity to 40 percent of natural background would be on a much longer timescale (e.g., likely hundreds to thousands of years) such that they would be considered permanent TSRC.²”</i></p> <p>These statements imply Perpetua’s reclamation, restoration and rehabilitation plans will not be effective in establishing soil productivity within centuries to millennia let alone the 50-year allocation of the TSRC definition. In conflict with the Payette National Forest (PNF) Land and Resource Management Plan (LRMP) definition of soil productivity, the SDEIS defines measures of soil productivity as:</p> <p><i>“...development of a litter layer, biotic crust and/or A horizon (organic matter-enriched surface layer); development of soil structure to support water and air movement; physical and chemical weathering of coarse fragments to add soil fines and nutrients; and development of the soil food web, nutrient cycles, and microbial community, especially the mycorrhizal network.²”</i></p> <p>While these (and other) metrics are important to assess the capacity of soil to “...support the growth of specified plants, plant communities, or a sequence of plant communities.”, they are not contemplated in the PNF-LRMP as measures of soil productivity. PNF-LRMP defines soil productivity as:</p> <p><i>"Soil productivity includes the inherent capacity of a soil under management to support the growth of specified plants, plant communities, or a sequence of plant communities. Soil productivity may be expressed in terms of volume or weight/unit area/year, percent plant cover, or other measures of biomass accumulation."³</i></p> <p>This more appropriate definition of soil productivity is exemplified in PNF Huckleberry Landscape Restoration Project (HLRP) FEIS⁴. The HLRP FEIS recognizes the value of restoration, reclamation, and rehabilitation in analyzing TSRC as illustrated from the following excerpts.</p> <p><i>“These effects do not completely recover through natural processes, but soil productivity and hydrologic function can be recovered with the implementation of physical treatments, such as decompaction, recovery of topsoil, placement of organic material and revegetation.⁴”</i></p> <p><i>“Alternative 2 proposed activities would initiate recovery of soil productivity and reduce TSRC on 371 through obliteration of unneeded system and nonsystem roads, which accounts for a 0.74% reduction in</i></p>	SOI	The Forest Service assessment of soil conditions concluded that the timing for restoring soil conditions along with uncertainty in that timing warranted a Forest Plan Amendment as described in SDEIS Appendix A.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>TSRC within the analysis area. The construction of landings, primary skidtrails and new temporary roads (up to 34 miles, approximately 100 acres, 0.2% TSRC) associated with vegetation treatment activities would result in short-term increases in TSRC (<15 years). The required rehabilitation following use of these areas should result in no net gain in long-term TSRC. Additional reductions in TSRC would occur when existing skidtrails, landings, and roads in a TSRC condition are reused and then rehabilitated. New permanent road construction and road reroute construction totaling 17 acres would represent a 0.034% increase in TSRC within the analysis area. The proposed trail reroutes would include stabilization and rehabilitation of the existing trail areas following new construction, thus no net change in TSRC.4”</p> <p>“Restoration of existing roads, skid trails, and landings through obliteration would directly reduce TSRC (and DD) and improve soil conditions, processes, and functions in the harvest or fuels units by decompacting soils and adding CWD and other organic matter to the surface. Lloyd et al. (2013) observed improved infiltration rates and soil bulk densities on obliterated roads recover to values similar to never-roaded areas at 1, 5, and 10 years following obliteration. In this same study and time frame, soil organic matter, total carbon, and nitrogen pools and processes increased to levels similar to never-roaded surfaces. Road, skid trail and landing obliteration following reuse are expected to produce similar beneficial results and would also improve slope stability and decrease long-term erosion.4”</p> <p>Given the SGP reclamation and closure plan utilizes very similar and arguably more aggressive soil restoration and rehabilitation techniques than described in the PNF’s HLRP, the SGP SDEIS should recognize soil rehabilitation efforts as part of the TSRC analysis. Without recognition of the SGP reclamation and soils rehabilitation in the TSRC analysis there would appear to be a negative bias towards the SGP compared to the similar impacts and rehabilitation efforts recognized in the HLRP. Therefore, I request the FEIS TSRC analysis be revised to recognize all applicable aspects of the SGP restoration and reclamation plans. In doing so the PNF may find the SGP will be compliant with existing forest management plan TSRC thresholds of less than 5% and thus avoid a forest management plan amendment.</p>		
Daniel S. Kline	16484	3	<p>Regarding reclamation cover material quantities, the SDEIS notes the following.</p> <p>“The GM deficit is thus estimated at approximately 797,702 BCY (Tetra Tech 2021a). Options being considered by Perpetua for developing additional GM for the SGP include: utilizing materials from off-site borrow areas and supplementing additional salvage of GM through composting.2”</p> <p>The 2021 SGP Reclamation and Closure Plan (RCP) states that Yellow Pine Pit (YPP) glacial till will be used to offset the deficit along with growth media amendment of chipped wood and compost. The 2021 RCP also discredits utilizing offsite soils barrow sources. SDEIS Section 2.4.7.12 and Table 2.4-12 (pg 2-113) also notes the same YPP till source. Therefore, I request the Reclamation and Cover Materials section of the FEIS be revised to describe the correct proposed soils deficit offset found in the RCP and Section 2.4.7.12.</p>	SOI	The Final EIS has been revised per the comment.
Wasley, Dustin (Principal P.E., Haley Aldrich)	17633	4	<p>The closure plans for the project also employ best practices design measures including stockpiling and salvage of topsoil, and use of amendments to increase the volume of reclamation materials needed for closure. Certain conservation groups quoted in the media, such as ICL, have focused on the reclamation material deficit identified in the SDEIS as a major issue. It should be noted that there is currently a significant deficit of topsoil on the site in disturbed areas due to unregulated mining activities and that Perpetua has proposed to bulk up existing topsoil by blending and amending with compost and woodchips to address the shortfall. This approach will be effective and better than leaving the site as it is today.</p>	SOI	Comment noted. No response required.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	131	<p>4. The SDEIS lacks adequate suitability criteria for growth media</p> <p>Sustainable revegetation success depends on the quality of growth media (GM) and subjacent material that comprises the vegetation zone with regard to a number of physical, chemical and nutrient factors. According to the Soils Specialist Report (p. 13), when excavating and storing materials for growth media, “Tailings and contaminated soil and fill material from historical mining activities would be</p>	SOI	<p>Section 4.5.2.2 describes the suitability criteria for growth media.</p> <p>Identification of suitable material for growth media involves screening metal concentrations for comparison to baseline soil concentrations to exclude materials with metal concentrations beyond the range of baseline soil conditions from use as growth media. It is expected that growth media within the range of baseline soil conditions would have comparable leachability</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>identified through testing and visual observation and separated from suitable soils prior to and during soil excavation activities. Testing for contamination would focus on the presence and leachability of metals from these materials (e.g., arsenic, antimony, and mercury) (emphasis added). When encountered during GM/SBM salvage, these materials would be excavated separately and reprocessed, repurposed for construction purposes (if suitable), and/or disposed of into the TSF.” However, the suitability criteria for growth media (Soils Specialist Report, Table 2-3) doesn’t specify leachability criteria. What leachability criteria will be used, and how will it be applied?</p> <p>The SDEIS also lacks phytotoxicity suitability criteria and public health criteria for growth media. The Reclamation and Closure Plan does not include trace metal concentrations as part of the growth media suitability guidelines for plant growth. According to the Soils Specialist Report (p. 76), “Metal concentrations in growth media would be screened for comparison to baseline soil concentrations pre-reclamation per Forest Service requirements.” However, the specific baseline concentrations that would apply are not specified.</p> <p>The SDEIS must specify the baseline concentrations that would be used as suitability criteria for growth media, and whether that may affect the amount of available growth material, and not defer this information and analysis to another time.</p>		<p>and phytotoxicity properties based on the site soil surveys and observations of growth media performance in historical reclamation areas.</p> <p>The upper bounds for soil arsenic, antimony, and mercury concentrations for materials expected to support plant growth and development are provided in the Reclamation and Closure plan and described in Section 4.5.2.2.</p>
Idaho Regulatory Agencies	17718	5	<p>Suggest heading should be: Quantity, Quality, and Suitability of Growth Medium because only Growth Medium is then discussed. Throughout the document "soil" terms are not defined, or not adequately defined. For example, one has to infer that Growth Medium is a Reclamation Cover Material. Also, the document and supporting documents (Tetra Tech, 2020; 2021) use "soil" terms including Growth Media (Growth Medium is preferred); soil, soil bank material, mineral soil, etc. Provided are additional definitions in 7.3 Glossary, based on the supporting documents, and soil science standards in hopes of clarifying.</p>	SOI	Revisions accepted. Sections 3.5, 4.5 and 7.3 have been revised to clarify terminology.
Idaho Regulatory Agencies	17718	6	<p>The soil quantity and quality are both limited and rated as poor to fair. There are several key words in this section of the Executive Summary that are vague:</p> <p>Additionally, there would be a 797,702 bank cubic yards GM deficit at the mine site according to the balance calculations in the Reclamation Closure Plan. This deficit may be partially met with the surplus of material obtained from the Burntlog Route or could be met through....</p> <p>Thus, there is presently some uncertainty regarding the specific source of material to meet the identified GM deficits under either action alternative.</p> <p>However, Perpetua has committed to salvage the appropriate volume of GM and to create the volume of compost necessary as an amendment to provide suitable quality and quantity of the GM to cover the areas to be reclaimed. Perpetua has also committed to performance criteria tied to slope and soil stability, sediment, and vegetation cover, which would need to be met prior to release of a reclamation performance bond.</p> <p>What does “may be partially met or could be met” mean? It sounds as if this topic has not been fully researched and the project could proceed without a definitive plan. The soil quality and quantity will remain an issue throughout this project unless there are strict standards as to the appropriate volume of GM material, (how much is this and it’s already of poor or fair quality) the necessary volume of suitable compost (how much and who deems what is suitable?) this is to be added material to make it suitable for successful revegetation (successful to whom). The quantity and quality should be approved by the cooperating agencies. If it’s not available on site, then it should be hauled in. The cost factor is not a consideration for this NEPA review.</p>	SOI	<p>The SDEIS acknowledges the uncertainty in the sourcing of reclamation cover materials which could be derived from the different sources identified. References to "partially met" and "could be met" refer to the sourcing of materials from a specific source rather than overall attainment of reclamation goals and standards.</p> <p>Suitability of compost would be dependent on its ability to meet the standards established for placement as reclamation cover material and then attainment of reclamation standards for physical stability and revegetation.</p>
Idaho Regulatory Agencies	17718	14	Please define "suitable growth media," or delete "Suitable."	SOI	The "Suitable" adjective has been removed at this location which is a description of stockpile locations. Suitability of growth media is discussed in Section 4.5.2.2.
Idaho Regulatory Agencies	17718	71	Title is incorrect in comparison to the paragraph information, which also needs editing. The quote "productive condition" is not stated in IDAPA, but was copied from the IDL website. Background: IDL has been given the authority to regulate surface mining in Idaho by two legislative proclamations having	SOI	The description of the Idaho Administrative Procedures Act and IDL authority has been revised per the comment.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			the force of law: Idaho Statutory law (cited as Idaho Code or I.C.), and Idaho Administrative Code via the Idaho Administrative Procedures Act (cited as the acronym IDAPA). Idaho Code, Title 47, Chapter 15, et seq. – Mined Land Reclamation, is a Statutory law passed by the Idaho State legislature. IDAPA 20.03.02 – Rules Governing Mined Land Reclamation is the final rule that must be approved yearly by the Idaho State legislature so that IDL can administer Idaho Code, Title 47, Ch. 15, et seq. Please edit the underlined heading and paragraph to : <i>Idaho Mined Land Reclamation Act and Rules Governing Mined Land Reclamation: The Idaho Department of Lands (IDL) has the authority to regulate all surface mining in Idaho by: Idaho Mined Land Reclamation Act (Idaho Code, Title 47, Chapter 15, et seq.); and Rules Governing Mined Land Reclamation (Idaho Administrative Procedures Act (IDAPA) 20.03.02). Reclamation is the process of restoring an area affected by a mining operation or cyanidation facility to its original or another beneficial use, considering previous uses, possible future uses, and surrounding topography. The objective is to re-establish a diverse, self-perpetuating plant community, and to minimize erosion, remove hazards, and maintain water quality (IDAPA 20.03.02.010.20). To help accomplish Reclamation requires Best Management Practices (BMP), which are practices, techniques or measures developed or identified by IDL and identified in the state water quality management plan which are determined to be a cost effective and practicable means of preventing or reducing pollutants generated from nonpoint sources to a level compatible with water quality goals (IDAPA 20.03.02.010.03). These BMPs have also been published as a manual (IDL, 1992). This manual also is referenced in the Payette Forest Plan management direction (Mineral and Geology Resources) as a guide for evaluating the completeness of reclamation plans with respect to mitigating water quality effects.</i>		
Idaho Regulatory Agencies	17718	72	"Metasediments" is a misnomer. The correct term is <i>metasedimentary rocks</i> , which, at the Project site are types of Paleozoic metamorphic rocks. Metasedimentary rock is used in other parts of the document.	SOI	The term "metasediments" has been replaced with "metasedimentary rock" at locations where it occurs in the text.
Idaho Regulatory Agencies	17718	73	Heading is "Operation Area Boundary" but it is not defined or in Glossary. Please note that a generic operation area is defined by its boundary, but an operation area boundary is NOT an area, but simply the boundary of the area. This error occurs in other parts of the document.	SOI	The header has been modified to "Operational Area". The term Operations Area Boundary has been added to the glossary.
Idaho Regulatory Agencies	17718	74	"Soil Contamination/Chemistry" Please, especially for headings, try and not use the slash. This section should be called <i>Soil Chemistry</i> .	SOI	Section header revised to Soil Chemistry.
Idaho Regulatory Agencies	17718	75	Please define Operations Area Boundary.	SOI	The term Operations Area Boundary has been added to the glossary.
Idaho Regulatory Agencies	17718	80	<p>Comment: It has been documented by Perpetua (Tetra Tech, 2021a, Appendix B, Section 6) and noted by the Idaho Department of Lands throughout the review of technical reports, DEIS, and this SDEIS process, that the quantity and quality of Reclamation Cover Material (RCM) is lacking. Vegetation success has been, is, and will continue to be an ongoing problem to return the disturbed area to productive conditions, if the quantity and quality of RCM isn't addressed properly. This will likely mean hauling in the predicted deficit of a quality material from offsite. This will be an increased cost; however will be needed for successful reclamation. Perpetua continues to claim that the only way to restore the Stibnite area to a productive site is by mining antimony and gold, followed by successful restoration and reclamation (see Perpetua website).</p> <p>Without the quantity and quality of RCM to ensure vegetative success, many parts of the proposed Restoration and Reclamation will fail. One of the areas of great concern is with the predicted water temperatures to ensure fish survival. Without successful revegetation resulting in shading over the streams, temperatures will only rise. While the best seed bank material and growth media on site is to be utilized for reclamation along riparian corridors, many of the streams will not be reclaimed until the end of the project. Both the seedbank and growth media will have been stockpiled for long periods of time, greatly reducing viability (especially of the seed bank material). Revegetation on slopes will reduce erosion and sediment entering the streams, but without quality RCM to provide successful revegetation, erosion and sedimentation will continue to be a problem. Water quality, already poor will continue to be impacted by using poor RCM which contain high amounts of metals, which will continue to leach into seeps and streams. Photos from the Perpetua website portrays extremely optimistic successful restoration</p>	SOI	Implementation of the Reclamation Closure Plan would include revegetation performance monitoring. Further, a reclamation bond would be established and in place prior to construction. This bond would remain in place through the satisfactory completion of reclamation activities including revegetation.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			and reclamation. However, Perpetua never states how long it will be for successful restoration and reclamation. Perpetua only states that they will “establish vegetation”, which leads the reader to believe it may not reach what is considered “successful revegetation” as per IDAPA 20.03.02, 140.11. a. and b. In reality, it may take many decades to achieve, if it happens at all.		
Idaho Regulatory Agencies	17718	81	"The 2021 MMP consists of a 3-year construction period, approximately 12-year production period, 5-year closure period, and 5-year plus post-closure period. " Comment: Many areas of reclamation will continue for longer than a 5-year plus post-mill operations (Closure refers to cyanidation facilities). Please considered this rewrite to correctly relate the "approximations", etc.: The 2021 MMP assumes that it will take: 3-years for mine construction, 12 years to mine, produce, and concentrate ore; 5 years to decontaminate and remove mine facilities; and 5 years to perform much of the reclamation. However, final reclamation will take at least an additional 40 years, and potentially much longer.	SOI	The text has been revised to read "The 2021 MMP consists of a 3-year construction period, approximately 12-year production period, 5-year closure period, and a post-closure period estimated to be approximately 40 years."
Idaho Regulatory Agencies	17718	82	"All the SGP-related disturbance at the mine site would be subject to reclamation activities, with the exception of approximately 278 acres associated with the Hangar Flats high walls, the West End pit lake and high walls, Yellow Pine pit high walls, the Stibnite Lake feature, plus the Midnight, West End, and Plant Site ponds. These areas would remain a permanent commitment of soil resources (a large portion of which would occur on private patented mining claims). For all other areas in the activity area, disturbance would be subject to the reclamation activities detailed in the Reclamation and Closure Plan (Tetra Tech 2019a, 2021a)." <u>Comment:</u> While the Forest Service may look at the 278-acre disturbances as a total soil resource commitment (TSRC), the IDL will require grading, recontouring and seeding where applicable on all disturbed land. Highwall benches can be reclaimed by hauling in quality Growth Medium and reseeding with grasses, shrubs, and conifers. Ponds and lake banks can be re-contoured, re-graded, and seeded to prevent erosion. Proper drainage systems need to be built into the lake and pond configuration to reduce sedimentation. Please note that the Idaho Department of Lands will require an application for mining operations under Idaho Administrative Procedures Act 20.03.02 – 070: Application Procedure and Requirements For Other Mining Operations Including Hardrock, Underground and Phosphate Mining. The IDL will also require an application under IDAPA 20.03.02 - 071: Application Procedure and Requirements for Permanent Closure of Cyanidation Facilities. Reclamation activities will be subject IDAPA 20.03.02, and not just disturbance subject to the reclamation activities detailed in the Reclamation and Closure Plan (Tetra Tech 2019a, 2021a).	SOI	Comment noted. All applicable IDL requirements would be required to be implemented and adhered to for the Project.
Idaho Regulatory Agencies	17718	83	"The duration of impacts would vary by component based on the disturbance and reclamation schedule. Most disturbances would be initiated during the construction or early production phase and continue for <u>a number of years</u> until final reclamation is initiated. A select number of components would be reclaimed concurrently during active mine operations, so that duration of impacts would be lessened. Nevertheless, this analysis assumes recovery of greater than 40 percent soil productivity of natural background within a 50-year timeframe would not occur (due to the nature of disturbance and the conditions at the site) and, therefore, the duration of impacts would be longer-term, well beyond the 50-year threshold. For the TSF and TSF Buttress, where selected development rock would serve as the rooting zone for reclamation-related planting instead of native regolith, recovery of soil productivity to 40 percent of natural background would be on a much longer timescale (e.g., likely <u>centuries to millennia</u>)" Please provide an estimate of years for the first underlined section. As per the Project Phases, Final Reclamation may not occur for 40 or more years after the mill is shut down. The second underlined section states the consequences of having poor quality Growth Medium. For successful Reclamation, vegetation success is paramount. Please also note that the West End Pit as it remains today, is a precursor to what will be left by Perpetua for other areas, if quality Growth Medium is not made available from a source other than the Project area.	SOI	The text has been revised to read "... or early production phase and continue for an estimated seven years post-closure until final reclamation is initiated for all mine components."
Idaho Regulatory Agencies	17718	84	The correct quantity or quality of Growth Medium is necessary to support reclamation of a mining project to produce the outcome stated on Perpetua Resources website (“Perpetua Resources developed closure and restoration plans with the objective to establish a sustainable fishery with enhanced habitat to support natural populations of salmon, steelhead, and bull trout; improve water quality; establish	SOI	Comment noted. No response required.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>vegetation; and enhance wildlife habitat, all of which contribute to a self-sustaining and productive ecosystem. Closure, reclamation and restoration activities will achieve post-mining land uses of wildlife and fisheries habitat and dispersed recreation at the mine site..."</p> <p>Reclamation success is more likely to be achieved by suppling the quality and quantity of GM to the SGP from an approved off-site source. The material should not be hauled to the site until needed to avoid setting in a stockpile for 1 to 40 plus years. While some onsite material could be mixed with off site material, the material at the SGP would need to be tested for trace minerals before being mixed and used as GM.</p>		
Idaho Regulatory Agencies	17718	85	Mitigation to cover the predicted gap in RCM is needed to help ensure that the gap is adequately addressed in future reclamation cost estimates. Requiring a specific volume of excess RCM from the Burnt Log Route to be hauled to the site and stockpiled during construction is one example.	SOI	Comment noted. No response required.
Jack McManus	18036	2	<p>The Stibnite Pit obviously needs to be repaired. Despite there being loads of other problems, one of the main holdbacks to current recovery of the historical pit is a lack of carbonic soil available out there. We need big piles of trees, wood chips, pine needles, etc. Luckily, we have a problem with too much of that on our hands already. The County 'Transfer Site' is also trying to deal with a massive growing pile of 'woody debris' in their phacility out by Jug Mountain. Let's see some intergovernmental cooperation, and check one of the boxes along the path to recovery!</p> <p>Lets use the material which has been prepared for us, and go recover that soil!</p>	SOI	Agreements between Perpetua and Valley County regarding the use of woody debris from the county transfer site is outside the purview of the Forest Service.
Lynn Oliver	18565	1	<p>From my experience as a past mine geologist, when reclamation finally commences there always seems to be a shortage of soil. The analysis would be improved if this component could be included within the TSRC analysis area in Section 3.5. It would be good to know how much is actually available on private land.</p> <p>Final Forest Service approval of the Modified Mine Plan should include the ability to bring in suitable soil from private land located off-site if needed. While costs would be excessive, this is a reasonable mitigation that would alleviate public concern for the success of reclamation activities in riparian areas. Hopefully, there is enough stockpiled soil from mining operations that this wouldn't be required.</p>	SOI	<p>Soils on private lands are not included in the TSRC analysis because that metric is for application to effects on Forest Service lands. Instead, information regarding the availability of soils is summarized in the SDEIS references to the Soils Specialist Report and the Project Reclamation Closure Plan (Table 3-8). The private land parcels for salvage of reclamation cover materials are associated with the plant site, Hangar Flats pit, Yellow Pine pit, and West End pit. These total approximately 27% of the planned soil salvage.</p> <p>The Reclamation Closure Plan identifies a sufficient volume of reclamation cover material to meet Project needs. The plan also allows for adaptive management for reclamation cover materials in the future event that the planned materials are not suitable for use or have an insufficient volume.</p>
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	3	Addressing suitability of soils for reclamation and effects of soil contaminants on surface water quality.	SOI	Topic header. No response required.
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	23	<p>Reclamation Cover Material</p> <p>Table 2.4.-12 in the DSEIS indicates that reclamation cover material (e.g., growth media) used in places including but not limited to the TSF and tailings storage facility buttress (TSFB) would be evaluated for contaminants prior to use during reclamation. Acceptable metal/contaminant concentrations and sampling and testing would be documented in a sampling and analysis plan developed prior to reclamation.</p> <p>EPA recommends that the FEIS disclose the concentration limits that would be required by the Forest Service since these are directly relevant to the evaluation of environmental impacts for the project, including the analysis of the availability of and suitability of cover material (metals) and the analysis of potential reclamation and closure/post- closure impacts to wetlands, waters, wildlife, aquatic resources, and public health in subsequent EIS sections.</p> <p>We have provided this same comment on previous versions of this section and the NEPA specialist report and reiterate the recommendation to disclose this information to support conclusions regarding impacts and mitigation effectiveness.</p>	SOI	<p>Section 4.5.2.2 describes the suitability criteria for growth media.</p> <p>Identification of suitable material for growth media involves screening metal concentrations for comparison to baseline soil concentrations to exclude materials with metal concentrations beyond the range of baseline soil conditions from use as growth media. It is expected that growth media within the range of baseline soil conditions would have comparable leachability and phytotoxicity properties based on the site soil surveys and observations of growth media performance in historical reclamation areas.</p> <p>The upper bounds for soil arsenic, antimony, and mercury concentrations for materials expected to support plant growth and development are provided in the Reclamation and Closure plan and described in Section 4.5.2.2.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	24	Suitable Soil Types for Reclamation Under Suitable Soil Types for Reclamation, the DSEIS states “[t]he soils in this SMU [soil map unit type halosparists (cTH)] also have elevated antimony, arsenic, and mercury concentrations (Tetra Tech 2021a).” ¹⁵ EPA recommends the FEIS discuss how soils with elevated concentrations of antimony, arsenic and mercury will impact predicted water quality concentrations of these contaminants. EPA also recommends specifying whether these values are elevated when compared to other background soils or in relation to soil criteria.	SOI	Section 4.5.2.2 describes the suitability criteria for growth media. Identification of suitable material for growth media involves screening metal concentrations for comparison to baseline soil concentrations to exclude materials with metal concentrations beyond the range of baseline soil conditions from use as growth media. It is expected that growth media within the range of baseline soil conditions would have comparable leachability and phytotoxicity properties based on the site soil surveys and observations of growth media performance in historical reclamation areas. The upper bounds for soil arsenic, antimony, and mercury concentrations for materials expected to support plant growth and development are provided in the Reclamation and Closure plan and described in Section 4.5.2.2.
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	25	Soil Contamination/Chemistry The DSEIS states “[t]he mean concentrations of antimony (14.88 ppm within a range of 0.04 to 2,580 ppm) and mercury (0.972 ppm within a range of 0.005 to 283 ppm) from the samples are high but are still within the highest screening-level phytotoxicity criteria concentrations from various literature references and federal agencies in U.S. and Canada cited in the Reclamation and Closure Plan (Tetra Tech 2021a).” While these concentrations may be below phytotoxicity criteria, EPA recommends the FEIS evaluate how elevated soil concentrations will impact surface water quality in the Environmental Consequences section of the FEIS.	SOI	Section 4.5.2.2 describes the suitability criteria for growth media. Identification of suitable material for growth media involves screening metal concentrations for comparison to baseline soil concentrations to exclude materials with metal concentrations beyond the range of baseline soil conditions from use as growth media. It is expected that growth media within the range of baseline soil conditions would have comparable leachability and phytotoxicity properties based on the site soil surveys and observations of growth media performance in historical reclamation areas. The upper bounds for soil arsenic, antimony, and mercury concentrations for materials expected to support plant growth and development are provided in the Reclamation and Closure plan and described in Section 4.5.2.2.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	632	" <i>The effects of past mining activities and their long-term impacts to soils would remain except for the removal of legacy mine waste materials under Phase I of the ASAOC.</i> " Please specify what these impacts (effects) are.	SOI	The text has been revised to "The long-term impacts of past mining activities on soil chemistry and metal concentrations would remain ..."
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	633	" <i>Although none of the RFFAs identified in Table 5.1-3, except for the future geophysical work along the Burntlog Route, would physically overlap with the action alternative disturbance footprints, forest management, motorized use of road systems, fire suppression, prescribed fire and wildfire, dispersed camping, fishing, and hunting activities would continue in the CEA and vicinity, which would continue to utilize dedicated facilities (areas of TSRC) or contribute to incremental DD effects.</i> <i>Under the No Action Alternative, Perpetua would continue to comply with reclamation and monitoring commitments included in the applicable Golden Meadows Exploration Project Plan of Operations and EA, which include reclamation of the drill pads and temporary roads by backfilling, re-contouring, and seeding using standard reclamation practices; however, as described in the Golden Meadows EA, the exploration and subsequent reclamation activities would have an insignificant direct effect to geology and soils and therefore an insignificant cumulative contribution to effects upon soils and RCM.</i> " Please define TSRC, DD, and RCM here for reader.	SOI	Definitions for the TSRC, DD, and RCM acronyms were previously provided in earlier chapters and to be consistent with all acronyms, once they are first used and defined, they are not refined in other sections and/or chapters. No change made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	634	" <i>Although none of the RFFAs identified in Table 5.1-3, except for the future geophysical work along the Burntlog Route, would physically overlap with the action alternative disturbance footprints, forest management, motorized use of road systems, fire suppression, prescribed fire and wildfire, dispersed camping, fishing, and hunting activities would continue in the CEA and vicinity, which would continue to utilize dedicated facilities (areas of TSRC) or contribute to incremental DD effects.</i> " Please clarify the level of incremental impacts, and use defined Impact Definitions in cumulative impact analysis.	SOI	The text has been revised to read "(areas of TSRC) or contribute to measurable but small-scale DD effects in instances where these activities did not occur on existing disturbance."
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	635	" <i>however, as described in the Golden Meadows EA, the exploration and subsequent reclamation activities would have an insignificant direct effect to geology and soils and therefore an insignificant</i>	SOI	Insignificant is defined per the criteria for approval of a project under an Environmental Assessment via the issuance of its Decision Record and Finding of No Significant Impact.

Resources Idaho, Inc.)					
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	224	"The mean concentration of arsenic (115 ppm) ...". Recommend adding the range of arsenic concentrations here to be more informative (i.e., "..., with a range of 0.22 to 7380 ppm...").	SOI	The ranges of soil arsenic concentrations has been added.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	225	"...creation of growth media through composting (Tetra Tech 2019a)". Throughout this section, this reference should be Tetra Tech 2021a. The 2019 RCP has been superseded by the 2021 version which is revised to the MMP.	SOI	The reference has been added or updated depending on whether the 2019 RCP contains additional information.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	226	"...creation of growth media through composting (Tetra Tech 2019a)". Suggest replacing this passage with: "...to offset the anticipated growth media deficit by using unconsolidated glacial till and colluvium/alluvium from the Yellow Pine Pit (Tetra Tech 2021a)."	SOI	Revision accepted.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	227	"SGP-related TSRC within the PNF activity area under the 2021 MMP would total approximately 1,302 acres, with approximately 104 of these acres occurring over areas of existing TSRC". The 104 ac value seems to be incorrect per the table (904 acres). Please correct.	SOI	Revision accepted.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	228	"The magnitude of impacts to soil resources within the PNF activity area includes excavation, grading, or filling of 1,457 acres (approximately 120 acres of which are already disturbed...". The 120 acre value seems inconsistent with table and value reported in Paragraph 2 of this page. Please verify and correct if needed.	SOI	Revision accepted.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	229	"Final reclamation of the new transmission line corridor from the Johnson Creek Substation to the SGP would occur during the closure and reclamation phase beginning after Mine Year 15". The 2021 RCP states that electrical transmission line will be removed and reclaimed when no longer needed to power the water treatment facilities located at the Project site. This statement regarding mine year 15 is erroneous and should be corrected.	SOI	The timing for reclamation has been corrected.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	230	Full paragraph 4 - Reclamation Cover Materials. RCM is not restricted exclusively to GM (and SBM). Instead, RCM will also be composed of one or more of the following materials: development rock, YPP Till, or other materials that are non-PAG/ML and meet the Root Zone Material Suitability Guidelines; development rock, YPP Till, or other materials that are non-PAG/ML and meet the Root Zone Material Suitability Guidelines; natural regolith/random cut/fill; streambed material; and rock armoring layers. This and other sections of the SDEIS should be revised according to the definition of RCM presented in this comment and inferred in the RCP.	SOI	Text has been revised to read "Suitable RCM within the Operations Area Boundary would be salvaged for subsequent use in reclamation. Salvaged soil material would come ... horizons. In addition to soils that would be predominantly used as seed bed material and growth material, other materials used in facility covers would be derived from Yellow Pine pit till and other mined materials that are non-PAG / non-metal leaching and meeting the suitability guidelines. GMSs would be..."
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	231	Please validate reported growth media volumes with values reported in Tetra Tech 2021a.	SOI	The value of 1,658,075 BCY was revised to 1,657,246 BCY and the value of 797,702 BCY was revised to 796,873 BCY to match Table 3-9 of Tetra Tech 2021a.

Resources Idaho, Inc.)					
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	232	"Options being considered by Perpetua for developing additional GM for the SGP include: utilizing materials from off-site borrow areas and supplementing additional salvage of GM through composting ". This statement is a remnant from an outdated RCP and the 2020 DEIS. The 2021 RCP states Yellow Pine Pit glacial till will be used to offset the deficit along with growth media amendment of chipped wood and compost. The 2021 RCP also discredits utilizing offsite soils borrow sources. SDEIS Section 2.4.7.12 and Table 2.4-12 (pg. 2-113) of this document notes the same YPP till source referenced in the 2021 RCP (Tetra Tech 2021a).	SOI	The text has been revised to replace off-site borrow areas with Yellow Pine pit glacial till.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	233	"This small amount of compost is not expected to provide sufficient long-term benefits to the GM that would be important for revegetation ". Please remove. This statement is speculative and is not presented with any supporting scientific data.	SOI	The text has been revised to "This small amount of compost, corresponding to 0.25 inches of compost mixed into 6 inches of GM, is not expected to provide sufficient ..."
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	234	"These stockpiles would be up to 200 feet tall, and the time between GM salvage and placement would vary greatly between different SGP facilities but could remain in stockpiles for as long as 1 to 42 years... "This is not accurately characterized; all but a few very small areas associated with long-term water treatment will be reclaimed by mine year 24. Additionally, the Fiddle Creek GM stockpile footprint is scheduled to be reclaimed and restored in mine year 23. See 2021 RCP (Tetra Tech 2021a).	SOI	42 years has been replaced with 24 years.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	235	"Metal concentrations in growth media would be screened for comparison to baseline soil concentrations pre-reclamation per Forest Service requirements." All native soils (not previously disturbed) salvaged for use as growth media have an inherent metals concentration which is those soil's baseline condition. Therefore, this SDEIS statement, implies that salvaged soils should be tested to determine if they abide by their own baseline conditions or to determine if they increase in metals concentration between salvage and reclamation (while in the GM stockpile). The intent of such screening should be targeted at non-native (previously disturbed) materials desired to be used as growth media and not the existing undisturbed soils salvaged for future reclamation use. Rephrase as follows. "Metal concentrations in non-native soils would be screened for comparison to native baseline soil concentrations". Also, add a reference for the statement of "...per Forest Service requirement" if this is to be used in the FEIS.	SOI	Revision not accepted. The screening requirement was developed due to the uncertainty in the suitability of reclamation cover materials both inherent and related to mining activity.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	236	"Planned screening of soils for arsenic content would reduce this uncertainty." Planned screening and rejection of some soils with sustainable existing native vegetation based on a screening level criteria set from off-site locations would be detrimental to reclamation success. Please clarify the basis for any proposed soil screening protocol.	SOI	Screening of soils to establish suitability for use as reclamation cover material would be conducted per Forest Service requirements. This basis is described in the preceding paragraphs.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	237	Full paragraph 3. The conclusion here is based on one reference. The conclusions of other peer-reviewed research publications should be considered before discounting the capacity of phosphatic fertilizers to increase plant tolerance to soil arsenic, which is not necessarily synonymous with arsenic solubility in soils. An example of this is Abbas, et. al. (2018) which states: "Many studies have shown that the addition of phosphate to plants under As stress has positive effects on plant growth and as such could increase plant tolerance against As stress. It is well established that both As and Pi have similar chemical properties and use the same carrier molecules for the uptake in plant roots via plasma membranes. Many genetic studies and physiological data from different species have revealed that As(V) and Pi are taken up by the same transporters." Abbas, et. al. (2018) Arsenic Uptake, Toxicity, Detoxification, and Speciation in Plants: Physiological, Biochemical, and Molecular Aspects. <i>Int J Environ Res Public Health.</i> 2018 Jan; 15(1): 59.	SOI	The NEPA analysis is obliged to note the potential effects of phosphate fertilizer usage on arsenic solubility. The text has been revised to acknowledge the Abbas et al. 2018 finding to read "The released arsenic becomes available for uptake by plants, and phytotoxicity has been observed in some instances, even after multiple wetting and drying cycles. In other instances, phosphate addition to plants has the effect of increasing plant tolerance against arsenic stress (Abbas et al. 2018)."

Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	239	"All the SGP-related disturbance at the mine site would be subject to reclamation activities, with the exception of approximately 278 acres associated with the Hangar Flats high walls, the West End pit lake and high walls, Yellow Pine pit high walls, the Stibnite Lake feature, plus the Midnight, West End, and Plant Site ponds (Tetra Tech 2019, 2021b)". This statement is inaccurate as presented as all contact water and plant site ponds will all be reclaimed. Similar to streams pit lakes such as West end and Stibnite lake should not be defined as TSRC given there is no pre-mining soils on these areas to be committed and they are on private lands	SOI	The Midnight, West End, and Plant site ponds have been removed from the list.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	238	(Payette Forest Plan GL-37 and 38) - Please define these citations.	SOI	GL-37 and 38 are items within the Payette National Forest Land and Resource Management Plan. The citation has been revised to Forest Service 2003a to reflect the source document.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	8	<p>Comments on Sections 3.5, 4.5 and the Soils and Reclamation Cover Materials Specialist Report are provided and include technical clarifications and recommended language revisions for clarity. A few comments are broadly applicable to these sections of the SDEIS and are provided below: The SDEIS references, in several instances, outdated versions of the Reclamation and Closure Plan (RCP).</p> <p>All references to the RCP should be Tetra Tech 2021a. The 2019 RCP has been superseded by the 2021 version which was revised based on the updated MMP (Refined Proposed Action [ModPRO2]). Section 4.5 of the SDEIS describes a deficit in Growth Media (GM) volumes needed to successfully complete all reclamation and restoration activities associated with the MMP. Inconsistent with previous section statements in the SDEIS, Section 4.5 also describes, inaccurately, how the GM deficit will be offset. To enhance accuracy of the MMP and consistency, all SDEIS references to offsetting the predicted GM deficit using material other than unconsolidated glacial till and colluvium/alluvium from the Yellow Pine pit should be revised to reflect that the predicted GM deficit will be offset using Yellow Pine pit materials as stated in SDEIS page 2-14, 2-90, 2-113.</p> <p>Perpetua Resources recognizes that existing TSRC within the Payette National Forest (PNF) and Boise National Forest (BNF), as calculated in the Soils and Reclamation Cover Materials Specialist Report (USFS, 2022) and illustrated in Section 4.5 of the SDEIS, are below the 5 percent threshold set in the PNF Forest Plan (Forest Service, 2003) and BNF Forest Plan (Forest Service, 2010). Perpetua Resources also recognizes the MMP includes dedicated facilities that will likely cause exceedance of the 5 percent threshold for TSRC, requiring a project specific amendment to the PNF and BNF Forest Plans (Forest Service, 2022). However, Perpetua Resources has developed the RCP so the majority of sitewide reclamation is achieved within a 50-year timeframe. Specifically, reclamation of approximately 20 percent, 40 percent, and 80 percent of the total area of planned new and re-disturbance associated with the Project will be initiated by project years 12, 16 and 25, respectively. The RCP applies a combination of quantitative and qualitative metrics of soil productivity, consistent with the BNF and PNF Forest Plans, that will be monitored to demonstrate that reclamation performance standards and bond release criteria are met. Meeting these standards and criteria defined in the RCP would indicate that the site has been reclaimed and soil productivity, as defined in the BNF and PNF Forest Plans (GL-35), is restored, at minimum, to 40 percent of natural background soil productivity in timeframes that are much shorter than assumed in the SDEIS. Perpetua Resources requests revisions to this section that recognize the value of the MMP reclamation and restoration work in reduction of TSRC as described in the Forest Management Plan's definitions of TSRC and Soil Productivity (PNF, 2003, Amended 2010).</p>	SOI	<p>The SDEIS utilized the 2019 and 2021 versions of the Reclamation Closure Plan in its analysis. Revisions have been made to reflect items where the 2021 version superseded the 2019 version.</p> <p>In Section 4.5.2.2, the analysis recognizes that reclamation activities would achieve their objectives on a shorter time scale (e.g., 5 to 10 years) but that in general, restoration of soil productivity occurs over a very long-time scale (centuries to millennia).</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Ruth Lewinski	19378	6	The soil contaminant (most notably for arsenic, antimony and mercury) values outlined in the SDEIS are significantly different from those in the DEIS. My biggest concern is with arsenic. Arsenic is a known carcinogen. In disturbing any of the soil at these sites, arsenic will be a notable component of the dust generated. This dust generated will not only be an air contaminant, but the silt will travel in stream beds. Onsite roadbeds will have this dust, which will be tracked along transport areas. Additional issues will be present with attempted dust suppression methods, using oil or water, and even road salt and gravel (Ice) as arsenic compounds are likely to form. I believe that the calculation presented underestimates the amount of arsenic contamination that will be present. Arsenic, antimony and mercury have known health risks, including having carcinogenic properties. The Forest Service should independently perform the emission calculations, air quality modeling, and risk assessment associated with arsenic, mercury and antimony contamination, as I do not believe that current estimates are accurate. These values need to be published and available to the public, especially along recreational corridors. Soil cleanup criteria should meet CERCLA guidelines.	SOI	<p>Section 4.3.2.2 describes the presence of arsenic and other metals in dust and Section 4.9.2.2 describes the presence of arsenic and other metals in water resources. These descriptions also inform Section 4.18.2.2 that describes potential health effects associated with arsenic in dust and water.</p> <p>Dust control measures employ application of water and gravel but do not employ application of oil and salt. These applications do not form arsenic compounds.</p> <p>The Forest Service reviewed the predictive models used to assess arsenic and other metal concentrations in dust and water resources and accepted those results for use in the SDEIS. These arsenic and metal concentrations are available through the SDEIS along with their source documents.</p> <p>The Forest Service’s consideration for the Project is based on comparison of arsenic and other metal concentrations to existing site conditions plus Federal and Idaho regulatory standards.</p>
David Chambers	17634-A	12	<p>4.5.2.2 2021 MMP – Reclamation Cover Materials</p> <p>The discussion in this section notes that the amount of cover/ growth material available for reclamation is only 48% of the amount of material that will be needed (p. 4-87). It is then noted that; “Options being considered by Perpetua for developing additional GM for the SGP include: utilizing materials from off-site borrow areas and supplementing additional salvage of GM through composting.”</p> <p>At this point, a commitment to supply the additional planned/required growth material is required. There is a danger is delaying this commitment until a later time, when there will obviously economic pressure to just say the amount of growth material available will be utilized to the “maximum extent possible”, a commitment seen by this reviewer in other EISs. If the plan/promise in the EIS is to provide the remaining cover/growth material, then the commitment to do so should be clear.</p>	SOI	The SDEIS has been revised to clarify the source of reclamation cover material, i.e., mined material from the Yellow Pine pit with addition of soil amendments.
Samuel Penney (Chairman)	19396	77	<p>3.5 Soils and Reclamation Cover Materials</p> <p>The SDEIS discloses that the total amount of new and re-distributed historical disturbance associated with the Project is approximately 1,675 acres, 137 of which 522 acres are highly disturbed. 138 Soils in the Project area are described as young, poorly developed, and occur on steep slopes. The SDEIS focuses on detrimental disturbance (“DD”), total soil resource commitment (“TSRC”), existing soil types, and quality of the reclamation cover materials.</p> <p>The relevant laws, regulations, policies, and plans in the SDEIS fail to include Payette and Boise Forest Plan management directions for soils. Chapter 3.5.3 should include management direction specific to soils, not just reference to achieving desired conditions for wildlife and wildlife habitat. For example, the SDEIS should recognize that the Plan’s desired conditions common to all resources includes that “[s]oils retain all or most of their natural productivity and are in a condition that promotes vegetative growths, hydrologic function, long-term nutrient cycling, and erosional stability.” And that ecosystems on the Forests “[a]re dynamic in nature and resilient and resistant to natural and man-caused disturbances.” The Forest Plans also have specific direction, including goals, objectives, standards, and guidelines outlined across several pages, which should be included in the SDEIS.</p> <p>Both Forest Plans include specific desired conditions that “[s]oil protective cover, soil organic matter, and coarse woody material are at levels that maintain or restore soil productivity and soil hydrologic functions where conditions are at risk or degraded. Soils also have adequate physical, biological, and chemical properties to support desired vegetation growth.” The management direction continues to describe desired conditions for large woody debris, and states that “...management actions result in no long-term degradation of soil, water, riparian, and aquatic resources conditions.” A goal shared by both Forests, but not mentioned in the SDEIS, is to “[m]aintain soil productivity and ecological processes where functioning properly, and restore where currently degraded. Maintain the physical, chemical, and biological properties of soils to support desired vegetation conditions and soil-hydrologic functions and processes within watersheds.” The Forestwide management direction for soils should provide the</p>	SOI	Section 3.5.3 describes the application of the Forest Plans and Forest Service Manuals to the Project. The EIS describes how the Project would not meet Forest Plan requirements regarding the duration of impacts to soils and therefore, would require a Forest Plan Amendment as described in Appendix A of the EIS.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			fundamental benchmarks for measuring a project's impacts to soils. The Forest needs to better explain how the proposed Project meets Forest Plan direction for soils.		
Samuel Penney (Chairman)	19396	79	The SDEIS also references Forest Service Manual 2550 Soil Management. Contrary to what is stated in the SDEIS, FSM 2550 does not include “[p]ractical methods to ensure that reclamation cover materials are suitable...” FSM 2550 sets the authorities, objectives, and policies for soil quality management and resource inventories at the planning and project levels. Under FSM 2550, the Forest Chief has the responsibility to ensure “...that soils on National Forest System lands are conserved and protected in order to maintain healthy watersheds that provide critical ecological services.” Due to the nature of the existing conditions and what is proposed, the Forest needs to analyze and monitor soil quality to ensure that ecologically sustainable soil management practices are being applied (as pursuant to FSM 2551.12). This includes estimating the type, amount, and degree of change to soil quality that the proposed activities may produce (activities such as, but not limited to stockpiling and adding compost, fertilizer, and any other amendments to the reclamation cover materials). While FSM 2550 does not directly spell out “[p]ractical methods to ensure that reclamation cover materials are suitable”, the Forest needs to draw upon the plethora of restoration and reclamation research generated from its own research and development professionals and collaborators and not rely solely on Perpetua’s proposed actions, most of which are not supported or justified with best available scientific information.	SOI	The text has been revised to remove "Practical methods to ensure that reclamation cover materials are suitable are summarized in the guidelines." Section 4.5.2.2 describes the potential effects of stockpiling, composting, and fertilizer addition as proposed by the Project's Reclamation Closure Plan. Reclamation cover materials would be subject to screening to assess their suitability at the time of closure and performance monitoring post-closure.
Samuel Penney (Chairman)	19396	80	Existing Soil Types The SDEIS describes existing conditions of soil types in the Project area, specifically soil types suitable and unsuitable for reclamation and for soils located across six broad areas of potential disturbance, access roads, and off-site facilities. The Tribe is concerned about legacy mining disturbance and that most soil types contain elevated levels of arsenic, antimony, and mercury. The Tribe understands that the soils in the project area naturally have high concentrations of metals, however, the environmental consequences of the proposed actions coupled with legacy disturbance outweigh concerns regarding natural concentrations. Just because natural conditions appear unsuitable or high does not justify or support the purpose and need. If baseline conditions are such that reclamation would be impossible, the Forest should reject the Project.	SOI	Based on the soil surveys conducted, the Forest Service did not conclude that reclamation would be impossible. However, there are materials on site that are not suitable for use as reclamation cover materials based on observation of their current performance as soil covers resulting in poor revegetation or non-attainment of growth media criteria. Therefore, these materials would be excluded from Project reclamation use.
Samuel Penney (Chairman)	19396	82	The SDEIS should also include an assessment of soil quality with respect to above and belowground biological components. What is the type, amount, and quality of vegetation growing on disturbed and undisturbed soils in the Project area? What is the type, amount, and quality of soil microorganisms in disturbed and undisturbed soils in the Project area? The Tribe feels that this information is necessary to understand the affected environment and environmental effects of each alternative.	SOI	Site soil surveys describe the current soil conditions and vegetation. These surveys quantified soil organic matter as an indicator of biological activity but did not describe microorganisms specifically. As described in SDEIS Section 4.5.2.2., Project activities such as soil salvage and stockpiling are expected to have a negative effect on microbial activity during construction and operations that would need to be addressed with soil management and amendments to stimulate microbial activity during closure and into post-closure. The presence of below-ground biological components is acknowledged in the Reclamation Closure Plan that would collect soil with high organic matter as seed bank material to facilitate the revegetation. The organic contents of soils were quantified via laboratory analyses of samples collected during 2017 and 2020 soil surveys.
Samuel Penney (Chairman)	19396	83	Existing Total Soil Resource Commitment and Detrimental Disturbance The SDEIS should reference the Forest Plan management direction (e.g., Guidelines and Standards) for TSRC and DD in Chapter 3.5 (e.g., Forest Plan Standard SWST03 requires, in an activity area where existing conditions of TSRC are below five percent of the area, management activities to leave the area in a condition of five percent or less TSRC following completion of the activities). Figure 3.5-1 needs to show the extent of existing TSRC and DD and provide information about those specific areas. The SDEIS needs to clarify the existing DD for each Forest.	SOI	Section 4.5.2.2 describes how the TSRC in the Project's activity area within the Payette National Forest would increase above 5% during the Project and how soil would recover over a long period of time. The duration of that recovery time is the subject of a Forest Plan Amendment because that timeframe is expected to exceed Forest Plan guidelines and standards for recovery time. The existing and proposed extents of TSRC are presented on Figure 4.5-1. The text has been revised to clarify the DD present in the Boise National Forest and the Payette National Forest.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Samuel Penney (Chairman)	19396	84	The SDEIS should also include the number of acres excluded from the TSRC analysis area, but would be impacted by SGP components, including acreage within IRAs, RNAs, Wilderness, and private land. How does the Forest disclose impacts to soils in these areas if they are not captured/categorized as DD or TSRC? Why didn't the Forest perform soil surveys for the existing or proposed transmission line ROW? If field investigations were not performed, how can the Forest determine existing DD and potential DD for each of the proposed actions? The SDEIS states that "[a]reas considered for TSRC are excluded from this (DD) requirement, but DD applies to vegetation clearing for new and upgraded utility corridors in areas that are available for multiple uses on NFS lands." What guidance and/or best available science does the Forest use to decipher whether soil disturbance is TSRC or DD? This guidance and decision-making process should be part of Chapter 3. Why is the TSRC activity area on the Boise NF so large (>76,000 acres), and why are some areas identified as TSRC where no project activities would occur? This would appear to minimize the project-affiliated TSRC. How is the TSRC activity area determined and delineated?	SOI	<p>The area excluded from the TSRC analysis is 2,888 acres.</p> <p>While not accounted for in a TSRC or DD calculation, Project disturbance on these excluded areas is described with regard to its effects on resources including soil reclamation (4.5.2.2), vegetation (4.10.2.2) and wildlife (4.13.2.2).</p> <p>The description of anticipated DD along the powerline route was developed based on an estimate of vegetation clearing (500 acres) and a conservative estimate that soil compaction and puddling would occur on 15% of the vegetation clearing area. The exclusion of TSRC from DD as described in Section 3.5.4.9 was not utilized in the effects analysis in Section 4.5.2.2 and has been removed from the revised text.</p> <p>The TSRC area within the Boise National Forest was defined based on the subbasins where Project-related activity is proposed to occur. In many instances, this Project activity could be limited (e.g., powerline improvement, repeater tower, etc.), however, those subbasins were included because they would experience some level of activity within them.</p>
Samuel Penney (Chairman)	19396	171	<p>4.5 Soils and Reclamation Cover Material</p> <p>Under the National Forest Management Act of 1976 ("NFMA"), all Forests are required to assess the impacts of management actions to ensure that they "will not produce substantial and permanent impairment of the productivity of the land." Perpetua's Project would create permanent adverse damage to soil resources. Under both action alternatives, soil productivity on more than 2,000 acres of land will not recover. This environmental consequence jeopardizes the recovery and health of the Tribe's treaty resources. The Tribe disagrees with Perpetua that they can leave the site in a better post-mine condition. The duration of impacts to soil resources would exceed the 50-year threshold for some actions which will prevent conditions from ever being better than if no further actions at the Project site were to occur.</p>	SOI	These effects are described in Section 4.5.2.2. While extended in duration, the extent of soil effects would be reduced by reclamation activities compared to the current unreclaimed condition of the site.
Samuel Penney (Chairman)	19396	172	The Forest Service Manual directs soil resource management to focus on ecological functions with an objective of maintaining or improving soil quality on National Forest Lands "to sustain ecological processes and function so that desired ecosystem services are provided in perpetuity" and with the policy to "[m]anage ecosystems to maintain or improve soil quality." Under both action alternatives, there would be long-term use of soil resources for mining purposes and the activities would completely remove native soil and there would be permanent loss of soil productivity. Without adequate soil resources, Tribal rights and interests will not be provided in perpetuity.	SOI	These effects are described in Section 4.5.2.2. Effects of reclamation on Tribal treaty rights access are described in Section 4.24.2.2, and are identified as a localized, long term, moderate to major impact.
Samuel Penney (Chairman)	19396	173	The SDEIS fails to evaluate impacts to soils from dust abatement applications and to fully incorporate and analyze components of the mitigation measures and the RCP. Several components of the RCP are not analyzed or considered in the SDEIS for soils, including stockpile locations, conditions, and specifications (e.g., slope construction should be less steep than 2.5H:1V considering the landscape), and the impact of using alternative growth media materials to achieve reclamation goals.	SOI	<p>Dust control applications are designed to minimize their effects on soils, by keeping the applications on the disturbed running surfaces of roadways.</p> <p>Soil stockpiling practices are described in Section 4.5.2.2 which acknowledges the potential for stockpiling to affect soil conditions. The primary location of the soil stockpile would be the Fiddle Growth Media Stockpile along with some smaller stockpile locations around the site (Figure 2.4-2). Best management practices for soil stockpiles to minimize the stockpiling effect on soil productivity are described in Section 4.5.2.2.</p>
Samuel Penney (Chairman)	19396	174	It is concerning that under both action alternatives, the Forests will be violating Forest Plan Standards for soil resources. The action alternatives would violate the following Standards on the Payette National Forest: SWST02, SWST03, MA13 MPC 3.1-1301, and MA13 MPC 3.2-1306. The action alternatives would violate the following Standards on the Boise National Forest: SWST02, MA20 MPC 3.1-2010, MA21 MPC 3.1-2108, MA19 MPC 3.2-1919, MA20 MPC 3.2-2010, MA21 MPC3.2-2113, MA20 MPC3.2-1914, MA20 MPC3.2-2005, MA21 MPC3.2-2108, and MA20 2006. The Forest needs to disclose the standards that will not be met, provide justification for the violations, and explain why the Forest is not proposing project-level amendments (except for SWST03 on the Payette).	SOI	The EIS acknowledges that the Project does not meet the duration requirements for soil impacts under the Forest Plan and proposes a project-level Forest Plan amendment to address that circumstance, recognizing that SWST03 is not met while the other soil standards are met.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Samuel Penney (Chairman)	19396	175	<p>Total Soils Resource Commitment</p> <p>The Forest needs to clarify whether the TSRC activity area includes IRAs and other special designated areas because the SDEIS includes conflicting statements. The amount of TSRC increases dramatically under both action alternatives. Recovery of greater than 40% soil productivity within a 50-y timeframe would be unlikely on more than 2,000 acres of land under both action alternatives. Development rock and unreclaimed areas (e.g., open pits) would be permanent TSRC. Because TSRC would exceed Payette Forest Plan direction, the Forest is proposing to waive Standard SWST03. The TSRC would increase from 3 to 17% on the Payette (1,457 acres). How can the Forest waive a Standard, and in doing so, what does that mean in terms of reclamation, post-mining land use, meeting Forest Plan management direction, and providing treaty resources in perpetuity? A large portion of the estimated TSRC would occur within the Operations Area Boundary. The SDEIS states that “[a]fter mine closure, hunting, fishing, and gathering areas would be restored through reclamation and revegetation of disturbed areas and wildlife would return.” If this statement is true, the Forest would not need to amend SWST03. The SDEIS also states in several places that “[t]here are no known types of natural resources (or subsistence resources) available for exercise of treaty rights in the Operations Area Boundary that are not available on the surrounding NFS lands.” The SDEIS discloses that the Forest is taking a conservative approach to the uncertainty in reclamation success by categorizing all project-related disturbances as TSRC (with the exception of the transmission line ROW because the Forest has determined this to be DD) and requesting an amendment to exceed the TSRC standard on the Payette. Uncertainty in reclamation success should be a reason for the Forest to reject the Project. The Forest is treating the TSRC impacted areas as sacrifice zones and furthermore, the Forest is uncertain about Perpetua’s ability to restore soil productivity. The Tribe finds the proposed actions and TSRC amendment unacceptable. It is unacceptable to the Tribe for the Forest to exceed a Forest Plan Standard, treat federal land upon which the Tribe has treaty rights as sacrifice areas, and allow a Project to exceed the TSRC Standard at the Forestwide scale (which would have adverse consequences to future foreseeable projects on the Forest). Granting an amendment to TSRC sets the precedent that mining companies can continue to permanently damage soil resources on NFS lands.</p>	SOI	<p>The SDEIS Section 4.5.2.2 specifies that IRAs and other special designated areas are not included in the TSRC calculation.</p> <p>Based in its analysis of soil productivity, the Forest Service proposes a Forest Plan Amendment to address the circumstance where recovery times are expected to be longer than the period specified in the Forest Plans.</p> <p>The Forest Service does not expect impacts to soil productivity to be permanent but does recognize a lengthy soil recovery period.</p>
Samuel Penney (Chairman)	19396	176	<p>Existing conditions detail that the DD analysis area occurs across both Forests, however environmental consequences to DD are only described for the Payette. The SDEIS needs to disclose impacts to DD on the Boise National Forest and clarify any violations of Forest Plan Standards (e.g., standard SWST02). Detrimental disturbance would occur on 500 acres of the transmission line ROW. Vegetation clearing would occur indefinitely along the transmission line and be maintained by Idaho Power Company. The Forest estimates that vegetation clearing in the transmission line ROW could result in DD as high as 16% (which exceeds Forest Plan Standards for DD). How did the Forest estimate this number without having performed a site survey along the existing and proposed utility line corridor? How is the Forest considering DD on timber resource areas when Perpetua has not provided an acreage estimate or indicated the location of forest resources intended for use? If all forested areas in the analysis area meeting the definition of timber resources are assumed to be harvested for sale during the Project’s construction and operations, what is the overlap for consequences to soils (i.e., would these areas fall under DD or TSRC)? What is the extent of DD on areas that have experienced wildfire in the past 20 years? The Project area spans 13 IRAs, and the SDEIS discloses that 740 acres of vegetation clearing would occur within six IRAs. How many of these acres are analyzed as DD?</p>	SOI	<p>A description of the distribution of DD between the Payette and Boise National Forests was added to the EIS. Of the total DD analyzed, 88% occurs in the BNF while 12% occurs in the PNF.</p> <p>The description of anticipated DD along the powerline route was developed based on an estimate of vegetation clearing (500 acres) and a conservative estimate that soil compaction and puddling would occur on 15% of the vegetation clearing area.</p> <p>SDEIS Tables 4.14-1 and 4.14-2 describe the locations where Project activities would remove timber. While merchantable timber may be sold, the Project Reclamation and Closure Plan utilizes salvaged timber for use as reclamation soil cover material. Therefore, timber resources are not assumed to be harvested for sale.</p> <p>The DD areas that have experienced wildfire in the past 20 years are along 22.7 linear miles off the DD areas or 54% of the area analyzed.</p> <p>Of the 740 acres of vegetation removed within six IRAs, 37 acres associated with 3.1 linear miles were analyzed as DD.</p>
Samuel Penney (Chairman)	19396	177	<p>Reclamation Cover Materials</p> <p>The Project would disturb approximately 3,564 acres of land (NFS and non-NFS land combined) under the preferred alternative. The Tribe is concerned about the reduced quantity and quality of reclamation cover materials. Project-related disturbance at the mine site under both action alternatives would be subjected to reclamation activities, except approximately 278 acres associated with the Hangar Flats high walls, the West End pit land and high walls, Yellow Pine pit high wall, the Stibnite Lake feature, plus the Midnight, West End, and Plant Site ponds. Soil productivity of un-reclaimed disturbance would be reduced to zero on 278 acres. For all other areas, disturbance would be subject to reclamation, which</p>	SOI	<p>The Reclamation Closure Plan sets suitability criteria for materials to be used for reclamation soil cover. Details on the specific properties of the amendments that would be used to achieve reclamation requirements from the Reclamation Closure Plan Sections 3.3.3.4, 3.3.3.5, and 3.3.4 have been added to the Final EIS.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			requires approximately 1,650,075 bank cubic yards ("BCY") of suitable soil material. Under both alternatives, there would not be enough suitable soil materials for reclamation (the deficit is >790,000 BCY). Perpetua proposes to use off-site materials (e.g., commercial compost from beef and dairy feedlots, weed-free alfalfa hay, straw mulch, "potentially other soil amendments", fertilizer and on-site materials (e.g., from food waste composting) to both replace the deficit and improve the quality of the reclamation cover materials. The SDEIS, however, lacks any analysis or best available science in regards to the proposed soil amendments and how they would comply with regulations, policies, and plans.		
Samuel Penney (Chairman)	19396	178	The Forest needs to determine the ecological and economic impacts of bringing off-site materials to a high-elevation landscape with naturally thin and poorly developed surface and subsurface layers.	SOI	Soil amendments would result in reclamation cover material characteristics that meet suitability criteria for use in site reclamation. These suitability criteria were based in part on site conditions. Therefore, use of the amendments would target reclaimed soil conditions that align with existing ecological and economic conditions associated with site soils. Amendments would need to meet Forest Service requirements (e.g., certified weed free).
Samuel Penney (Chairman)	19396	180	Perpetua also proposes to stockpile off-site compost—a counterproductive measure knowing that stockpiling can reduce soil quality.	SOI	Section 4.5.2.2 acknowledges the effects of stockpiling on soil productivity and describes Project practices to minimize those effects.
Samuel Penney (Chairman)	19396	181	The Tribe is also concerned about the elevated levels of metals (e.g., arsenic, antimony, and mercury) in the surface and subsurface soils and requests that the Forest require the screening of metals as part of the growth media suitability guidelines for plant growth. Trace metals are naturally elevated in surface soils in the Project area, which may hinder or limit vegetation establishment and growth. The Forest needs to take a hard look at the feasibility of reclamation and improvement of site productivity to ensure the continued existence of tribal rights and interests. The Forest needs to set the standards for reclamation and take advantage of the wealth and expertise of its own research professionals who have conducted numerous restoration and reclamation studies. Reclamation requirements shall be those reasonable, practicable, and necessary to attain standards. This should include measures of soil health (e.g., plant growth and composition, belowground microbial abundance and diversity, soil organic matter, soil texture, pH, etc.).	SOI	Reclamation cover materials would be screened to ensure that metal concentrations are within the range of existing conditions for the site and that suitability criteria based on metal concentrations are not exceeded. As described in SDEIS Section 4.5.2.2, project activities such as soil salvage and stockpiling are expected to have a negative effect on microbial activity during construction and operations that would need to be addressed with soil management and amendments to stimulate microbial activity during closure and into post-closure.
Samuel Penney (Chairman)	19396	406	5.5 Soils and Reclamation Cover Materials Under all alternatives, cumulative impacts to soils and reclamation cover materials include past and ongoing activities, such as, forest management, mining and mine reclamation, mineral exploration (e.g., Golden Meadows), motorized use, fire suppression, prescribed fire and wildfire, camping, boating, fishing, and hunting. Reasonably foreseeable future actions ("RFFA") include East Fork RAMP and South Fork Plunge Watershed Projects, but should also include projected mineral exploration activities (e.g., Horse Heaven Project and any anticipated exploration plans from Perpetua) that would create additional soil disturbance and add to the reclamation cover deficit within the Project area.	SOI	Section 5.5.2 describes the effects of cumulative disturbance on TSRC and the reclamation requirements for that disturbance. The EIS text was revised to specify the potential for reclamation cover material deficit associated with the reclamation requirements.
John Rygh		2	Where to start? How about the end game - "restoration". A key slogan of the proponent, Perpetua Resources, is "Restore the Site". I haven't heard that much lately. Perhaps they read the SDEIS and the accompanying Soil and Reclamation Specialist Report which make it abundantly clear that post-mining reclamation (much less anything approaching true ecological restoration) success will be extremely difficult if not impossible to achieve. Having thought a fair bit about restoration options out at Stibnite during my tenure with the Payette NF, this comes as no surprise to me. Basically, there is very little soil to work with out there to begin with and what is there is of poor quality. To make matters worse, the Forest Service proposes to amend the Forest Plan to allow the total destruction of 17% of the project area soil (measured by TSRC). Aldo Leopold had this to say about that: "The destruction of soil is the most fundamental kind of economic loss which the human race can suffer."	SOI	Comment noted. No response required.
John Rygh		4	Issue: Available RCM may not be of sufficient quantity or quality to achieve reclamation objectives of returning disturbed areas to productive conditions that sustain long-term wildlife, fisheries, land, and water resources, as defined in the Reclamation and Closure Plan (Tetra Tech 2021a).	SOI	The EIS has been revised to clarify the discussion regarding the use of Yellow Pine pit till as reclamation cover material to address the quantity of reclamation cover material required. The effects of stockpiling on soil quality and measures to minimize those effects are described in Section 4.5.2.2. The section also describes the arsenic, antimony, and mercury

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>This answer to this second issue is uncertain and raises a plethora of questions that are not encouraging. A host of negative factors suggest the ultimate success of reclamation (particularly revegetation efforts) I at the site is very much in doubt.</p> <p>Page 4-85 identifies the primary factors:</p> <p>There are three primary challenges associated with the quality and suitability of available RCM for the SGP: (1) the overall relatively poor existing quality of the upland soils (unit mixed typic cryorthents) that make up approximately 62 percent of the salvageable volume at the SGP and Burntlog Route; (2) the long-term stockpiling of material; and (3) the high background concentrations of metals in the soil.</p> <p>The deficit of salvageable soil is proposed to be addressed by a number of measures to improve both quantity and quality. These measures come up short on both counts. The quantity issue is addressed by bulking up the salvaged soils with wood chips to create what is termed "Growth Media" (GM). Depending upon a multitude of factors, the incorporation of wood chips into soil (particularly in the volumes proposed) can deplete plant-available nitrogen. The effects of anaerobic conditions expected in stockpiled GM (SDEIS, p. 46) on nitrogen cycling, microbial activity, and overall soil health should be evaluated in the context of wood chip addition. Even after addition of wood chips a GM deficit of roughly 800,000 cubic yards remains.</p> <p>The Reclamation Closure Plan (TetraTech, 2021a) proposes to use glacial till and colluvium/alluvium from the Yellow Pine pit to make up the deficit. This solution does not appear to be analysed in either the SDEIS or the Soils and Reclamation Cover Materials Specialist Report (U.S. Forest Service (Forest Service), 2022c). The Reclamation Closure Plan asserts that this material will be non-PAG/ML, but only provides average concentrations for arsenic, neglecting to mention antimony or mercury. Although the chemical suitability of this material is partially addressed, there is no mention of the other suitability criteria which likely rate it as fair to poor. This material would be stored separately from the other GM, but it is unclear how it will be used. If it is blended with the other GM when applied, this is likely to result in further decline in the suitability of already questionable quality GM. There is no explanation why 1.5 million BCV would be stored in the Fiddle GM stockpile when only 797,000 BCV are needed.</p> <p>Stockpiling of the GM is another problem. Two primary factors are at play here. The depth of burial and the time in stockpiles. Both have deleterious effects on soil productivity. The proposed stockpiles are up to 200 feet high with residence times of up to 42 years. Despite a handful of mitigation measures proposed, the SDEIS at p. 4-87 concludes: "Despite these measures the storage of GM within deep stockpiles for years would still result in the loss of soil productivity, which would affect the overall quality of this material at the time of placement. The quality of the usable GM leaves much to be desired from a physical, biological, and chemical standpoint. There is simply no getting around the fact that soils in the area are generally thin and of poor quality. Perpetua proposes to increase the organic matter content of the GM by adding alfalfa hay or compost to the GM (TetraTech, 2021a, p. 3-52). Both would be sourced out of southern Idaho, incurring significant transportation costs and GHG emissions. The Soils and Reclamation Cover Materials Specialist Report (p. 74) throws cold water on this idea, stating: "The RCP identifies 10 tons per acre of compost would be incorporated into the top 3 to 6 inches of GM; however, the volume specified is minimal, translating to less than 0.25 inch of compost to be mixed into 6 inches of GM. This small amount of compost is not expected to provide sufficient long-term benefits to the GM that would be important for revegetation. Fertilizer is considered as another possible means of improving GM quality, however there is disagreement as to how the addition of phosphate fertilizer might affect plant uptake of phytotoxic arsenic. The Reclamation Closure Plan (p. 3-57) suggests bioavailable arsenic could be reduced, while the Soils and Reclamation Cover Materials Specialist Report (p. 77) states that arsenic solubility could be increased. Statistically robust greenhouse testing of the performance of the main reclamation plant species in phosphate amended GM should be required prior to field application of these fertilizers. One consequence of the shortfall in GM and SBM volume is that the reclaimed areas have much less depth of GM spread over them than the depth of native material that is salvaged. For example, comparing numbers in Tables 3-5 and 3-7 in the Reclamation Closure Plan one can note that although salvageable SBM in wetlands extends to depths of up to two feet with another foot of suitable GM below that, the proposed application depth in all but one constructed wetland is a</p>		<p>concentrations in baseline soil materials which would form the basis for comparison for growth media.</p> <p>The Reclamation Closure Plan (Figure 3.4) calls for restored wetland areas to have at least 12 inches combined of seedbed material and growth material to support revegetation of those areas. The six-inch cover that combines seedbed material and growth material would be used to reclaim ancillary facilities such as diversions, roads, and ponds constructed in cut or fill of native material. Therefore, the soil cover is expected to support revegetation of those areas.</p> <p>The Final EIS includes a measure to assess the potential for metal mobilization by fertilizer prior to any application.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			mere 2 inches of SBM over 4 inches of GM. It seems likely that the productivity and functionality of these thinly veneered wetlands would be significantly reduced from the existing areas, yet no analysis of the influence of soil depth on wetlands function is included.		
John Rygh		5	The Soils and Reclamation Cover Materials Specialist Report (p. 74) states that coarse woody debris would be scattered over reclaimed land but offers no estimate of the total volume required or where it would be sourced.	SOI	Table 3-8 of the Reclamation Closure Plan describes the volume of chipped woody debris that would be sourced from each Project component. A summation and reference to this table has been added to the EIS.
John Rygh		7	<p>Soils throughout the project area contain elevated levels of arsenic, antimony, and mercury which can have phytotoxic effects on plants. Appendix B of the Reclamation Closure Plan (Tetra Tech, 2021) attempts to address this issue and determine element concentration values that would serve to establish chemical suitability guidelines for Root Zone Material (RTZ). Why such guidelines don't appear to be applicable to GM is unclear and should be explained. A statistical analysis of soil samples concludes that:</p> <p>"It is recommended that the upper-quantile values be used to assess whether on-site soils could support plant growth and development; therefore, the Chebyshev rule of inequality value for As, Hg and Sb of 450, 17 and 68 ppm, respectively, would likely provide a realistic yet conservative estimate of upper confidence limits of the mean concentrations in soil (EPA 2015; ITRC 2012) that would be expected to support plant growth and development on site." {p. B- 19}</p> <p>The average mercury and antimony content of proposed RTZ material falls below these limits, however much of the development rock proposed for use as RTZ material greatly exceeds the 450 ppm limit for arsenic. This inconvenient fact is then immediately discounted by noting that vegetation on a previously reclaimed area with higher arsenic levels appears to be doing well. Section 5 of Appendix B then goes on to present a different approach using vegetation survival to justify a much higher arsenic suitability value of 3000 ppm. This conclusion rests on the data from just three soil pits located in one of the oldest reclamation sites in the project area. Why weren't any of the other previously reclaimed sites such as the Spent Ore Disposal Area, the Garnet Pit, or any of the exploration phase test plots chosen as well? Most of these sites are not doing very well as far as vegetation establishment (Soils and Reclamation Cover Materials Specialist Report, p. 77). Absent any rationale for site choice, this approach suggests a strong bias in site selection and sample number.</p>	SOI	Suitability requirements were informed via inspection of reclaimed areas where revegetation has been successful. Inspection of these areas allows quantification of soil conditions where revegetation success was achieved for the purpose of setting quantitative criteria. Inspection of areas where revegetation has not been successful has lessons-learned utility for reclamation planning, but setting quantitative criteria based on absence of success has greater uncertainty than benchmarking based on revegetation success.

Noise

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Paula Schappachet	19138	1	According to a mining official in the business for over 30 years, the blasting from the mine will be heard around the lake!	NOI	<p>Noise effects of from blasting are expected to raise noise levels above the 55 dBA threshold for outdoor annoyance within 0.78 miles of the blasting activity.</p> <p>Warm Lake is more than 12 miles removed from blasting activity, located on the opposite site of an intervening mountain range. At this distance, noise affects from mine blasting are not anticipated to increase noise levels above the 55 dBA threshold.</p>
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	636	" <i>Noise</i> " Please describe the lack of cumulative noise impacts and that only concurrent noise would be cumulative, similar to what was described in the Air section.	NOI	The EIS currently reads that "Cumulative noise impacts typically occur when sensitive receivers are exposed to multiple noise sources at approximately the same time." This description is consistent with only concurrent noise being cumulative.
Alan Haslam (Vice President, Permitting,	19325	637	" <i>Noise related to access traffic and haul roads is of importance to persons along nearby public roads and in nearby residences.</i> " This is a direct impact rather than a cumulative one.	NOI	Revision accepted. This text has been revised to exclude this direct effect from the cumulative effects section.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Perpetua Resources Idaho, Inc.)					
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	638	"Past actions include activities such as mineral exploration, infrastructure development, and non-mining related actions are unlikely to present current noise impacts. " Please replace " are unlikely " to " would not contribute "	NOI	Revision accepted. This text has been revised to read that past actions would not contribute to current noise impacts.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	639	"The SGP has the greatest potential to contribute to cumulative noise impacts in the vicinity of the FCRNRW. However, given the mountainous topography, cumulative impacts would likely only occur if other ongoing or future actions in the general area occur within the same mountain valley or on nearby ridgelines." If data exists, please include whether the SGP noise added to the concurrent noise would breach any noise thresholds.	NOI	The current baseline noise conditions in the Burntlog Route area are described in Table 3.6-2. A baseline level of 40 dBA at that location reflects general ambient noise levels in the nearby wilderness areas. Direct effects from SGP construction and operations are not expected to raise noise levels in the FCRNRW above the recommended noise level of 55 dBA. Cumulative effects on the FCRNRW would be related to concurrent non-SGP activities that would raise noise levels about 55 dBA when combined with SGP activities.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	240	"Based on the Gazex explosive method, the maximum noise level would be 124.0 dBA at 100 feet away (Table 4.6-2), and at 50 feet away, the maximum noise level would be 130.0 dBA. A single blast at 50 feet away causes for a maximum noise level of 144.0 dBA. " These two values are conflicting dBA levels at 50 feet. Please only report whichever of these two values is correct.	NOI	Revision accepted. This text has been revised to remove "and at 50 feet away, the maximum noise level would be 130.0 dBA."
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	241	"There are approximately 7.5 missions per year, limiting the amount of avalanche abatement measures to a narrow timeframe of the year, with long-term , minor, and localized impacts. " Shouldn't this be short- term? Please replace " long-term " with " short-term ".	NOI	Revision accepted. This text has been revised to replace long-term with short-term because the period of avalanche abatement measures would be a short time period.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	9	Comments on applicable SDEIS sections include minimal technical clarifications for Section 4.6 only.	NOI	Comment noted. No response required.
Jesse Lutz	19386	12	<p>A note on noise impacts that were not considered during analysis. Noise - A noise that is 100 db at one meter will have an intensity of only 1/100 as much at ten meters. That's 20 decibels less, since a bel corresponds to a factor of ten. So at 10 meters the sound is 80 db. At 100m the intensity is down to 60 db, and so on. An SPL of 0 decibels roughly corresponds to the softest sound a human with good hearing can hear. So that would mean sound that is 10¹⁰ softer than 100 decibels. Given an inverse square law, that would correspond to 10⁵ times the original distance of one meter, or 100 km; much further than 1.5 miles or 5 miles which was used as a reference bubble to indicate potential sound impacts not only to Wilderness users but to any user of any type on National Forest Lands within and surrounding the project area - including all Wildlife species.</p> <p>Sound studies should be more plentiful, robust, in-depth, and be designed to represent accurate impacts caused by tools used while commencing mining practices - large pneumatic drills, trucks/vehicles of varying sizes and the required back up beeping sounds they create, idling equipment, generators, transmission lines, transformers, large capacity bull dozers and all associated equipment in building and maintaining roads during all weather conditions. Sounds travel differently during different atmospheric conditions and seasons therefore requiring higher levels of consideration and analysis to see honest representations of sound impacts stemming from this proposal.</p>	NOI	<p>As described in Table 3.6-2, a baseline condition of 40 dBA was used for ambient noise in wilderness areas. The 1.5 mile area is associated with the use of the 40 dBA baseline condition.</p> <p>Estimates for average noise levels with and without blasting were developed and described in Section 4.6.2.2 of the SDEIS. These estimates are based on the equipment proposed for project use.</p> <p>As noted in Section 4.6.2.2, ground absorption and atmospheric conditions in the project area were considered in forecasting the distances over which noise from the SGP would attenuate to 55 dBA.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Jesse Lutz	19386	14	According to the SDEIS - anyone recreating or using NFS lands within 1.5 miles of the proposed project area will be exposed to the sounds of day/night mining operations. How many acres is that compared to the actual acreage of the closed project mining area? Knowing this will represent a comparable percentage table of land impacts used by mining and those not being used by mining activities that are directly impacted at a 24 hour/7 days a week/365 day time frame.	NOI	Section 4.6.2.2 describes that noise from the SGP would attenuate to 55 dBA approximately 0.60 miles from the source of the activity. The area within 0.6 miles of the source of the activity. The area within 0.6 miles of project-related activities is approximately 9,627 acres.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	174	<p>Avalanche paths BKL-7, BKL-9, BKL-12, RC-1, and MCR-1 have anticipated explosive targets that are less than 1500 feet from the Frank Church River of No Return Wilderness boundary line. Not only is noise from helicopter flights to deliver explosive charges to these paths a potential impact but noise from the charges themselves is more apt to travel down slope into the valleys in the east side of Meadow Ridge and into the top of the Indian Creek drainage. As wolverines tend to avoid areas near roadways and individuals in the FCRNRW could be affected by traffic noise at 40 dBA, the proximity of these targets to the FCRNRW and the effect on wolverines in the FCRNRW should be assessed. At least one study has found noise levels above 100 dBA at 4,000 feet from Gazex explosions. Even if Gazex installations are not anticipated for the SGP, the SDEIS may underestimate the noise level attributed to avalanche control work. For instance, DAC (2021), while analyzing noise for case charging with 2 and 4 pounders, also assumes that charges delivered via helicopter will consist of “25 lbs of ammonium nitrate and 2 lbs booster per shot.” DAC (2021), at 47. Although 25-pound sacks of ANFO lobbed out of the side door of a helicopter are an effective tool for triggering large deep slab avalanches, they create a much larger explosion—and therefore higher level of dBA—which may be similar to Gazex explosions. During control missions conducted via helicopter, ANFO may be the preferred charge. Id. at 47. Indeed, Perpetua’s expert recommends “avalanche control via helicopter” Id. at 52. Yet, the SDEIS and Noise Specialist Report are silent on what is the dBA of 25 lbs of ammonium nitrate and 2 lbs booster. See SDEIS 4-114; Noise Specialist Report, at 33 (listing only three types of noise producing avalanche control tools). Nor does the SDEIS assert that such a charge is similar to a Gazex explosion. Because use of this avalanche control method appears likely based on DAC (2021)’s assessment, the SDEIS should quantify dBA for “avalanche control via helicopter” and assess those impacts. Moreover, given the complete silence on noise impacts to wildlife, the SDEIS should assess noise levels from avalanche control that extend into the FCRNRW. Importantly, as noted above, the underestimation of the frequency of control missions and that they are concentrated in specific areas should be considered when assessing the direct effects of noise from avalanche control work on wildlife. In sum, the Noise Specialist Report, which only analyzes impacts to humans, fails to address these points and any potential impacts to wildlife.</p> <p>As noted elsewhere in this letter, the SDEIS omits any analysis of mountain goats as a wildlife species impacted by the SGP. This is problematic with respect to avalanche control along the proposed Burntlog Route because mountain goats are particularly susceptible to disturbance from mechanized devices like helicopters (Côté 1996, Hurley 2004, Goldstein et al. 2005, Côté et al. 2013, Richard and Côté 2016). Explosive use during avalanche control may only exacerbate impacts to mountain goats and therefore must be addressed in the SDEIS. Notably IDFG has observed goats nearby on Murphy Peak, which is connected via a ridgeline to the Meadow Creek Ridge. Additionally, these surveys could underestimate mountain goat populations in the area. IDFG does not perform regular surveys of goats because their populations do not support any type of managed hunt. Mountain goats have also been observed in the area of Pinnacles on the border of GMUs 25 and 26, along the upper ends of Big Creek, Monumental Creek, and in West Fork Monumental Creek in GMU 26 (IDFG Mountain Goat Management Plan, 2019). These areas are near or adjacent to potential avalanche control targets along the Stibnite Road. The SDEIS fails to take a hard look at the actual effects and impacts to wildlife, including mountain goats and wolverines due to avalanche control work that will be necessary to maintain safe access to and from the mine site.</p>	NOI	<p>A description of helicopter avalanche control has been added to the Noise section of the Final EIS with efforts made to quantify noise levels from the use of ammonium nitrate fuel oil in addition to two- and four-pound cast boosters. Avalanche control via helicopter bombing would occur a minimum of one mile from the nearest residents (i.e., Yellow Pine). Based on the location of the SGP and the avalanche paths investigated, the probability of noise complaints would be expected to be low.</p> <p>Additional language was added to the Final EIS to clarify frequency estimates. Specifically, that frequency estimates for each route are an average of all paths on the route, with higher frequency paths likely needing more frequent mitigation than the average listed in Table 4.6-3. The # of charges per year is likely a better estimate of noise impacts.</p> <p>Depending on the location of avalanche control measures, noise at levels greater than 55 dBA could extend into the FCRNRW when controls are located within 2,000 feet of the FCRNRW.</p> <p>Noise effects on wildlife are described in Section 4.13.2.2 of the SDEIS.</p> <p>Mountain goats are not a PNF sensitive, MIS, or federally listed ESA species; therefore, an effects analysis is not required.</p>
Bonnie Gestring (Northwest Program Director,	17634	241	h. Effects of noise are not examined thoroughly or mitigated The SDEIS acknowledges that the Stibnite Gold Project will impact air quality and create noise impacts on the FCRNRW and nearby IRAs: Noise from mine related vehicles on the Johnson Creek Route during construction could decrease remoteness and increase the evidence of humans in Tamarack Creek drainage adjacent to the road. The Burntlog Route would decrease remoteness and increase the evidence of humans within Big Chief Creek drainage	NOI	The noise analysis accounted for ground absorption of sound which is related to topography and vegetation present. Therefore, the noise effects at local areas are reliably forecasted. Increased noise levels about threshold values are expected to be temporary, short-term exceedances related to passing road traffic.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Earthworks) and seven others			<p>during construction, operation, and closure and reclamation. Burntlog Route cut and fill slopes, repeater site access roads, and mine operation lighting could be visible to wilderness visitors within Big Chief drainage, Summit trail, and at higher elevations within the FCRNRW. Sounds from the construction, operation, and daily maintenance of Burntlog Route also could be audible in these areas. SDEIS 4-633. The Forest Service's noise analysis failed to take into account topography or vegetation which can have significant effects on sound propagation: Sound from SGP activities at recreation sites/areas is based on estimated noise that does not consider the effects of topography or vegetation on noise propagation. Therefore, the noise impacts presented in the analysis may be more extensive than would actually occur given the topography and vegetation present in the analysis area. (Recreation Resource Specialist Report, p. 13). Because these estimates did not consider topography or vegetation, the noise impacts presented in the analysis may also underestimate the actual effects, particularly in places where the topography may channel or concentrate sound or in areas with fewer trees and more grassy slopes or talus. Avalanche paths BKL-7, BKL-9, BKL-12, RC-1, and MCR-1 have anticipated explosive targets that are less than 1500 feet from the FCRNRW boundary line. Not only is noise from helicopter flights to deliver explosive charges to these paths a potential impact but noise from the charges themselves is more apt to travel down slope into the valleys in the east side of Meadow Ridge and into the top of the Indian Creek drainage. In terms of avoiding, minimizing or mitigating these effects, the Forest Service analysis essentially notes that the sound and light is going to go where it goes: The extent where the SGP facilities and access roads could change soundscapes or natural dark sky conditions is influenced by topography and weather. However, the Forest Service fails to note that the primary factor influencing these negative effects is the location of SGP facilities and access roads, which can be sited to reduce impacts. Furthermore, while the Special Designations Specialist Report lists several design features to reduce these impacts, these are listed as discretionary and at the proponent's discretion: To minimize adverse effects of noise to TEPC, MIS, or Sensitive species, where necessary and in accordance with MSHA and OSHA, the proponent could utilize actions in line with, but not limited to, the below:</p> <ul style="list-style-type: none"> ● Construction equipment engines would be equipped with adequate mufflers, intake silencers, and engine enclosures when feasible. ● When practicable, pumps, generators, and engines would be turned off when not in use. ● Temporary wooden structure could be erected around portions of the drill, pumps, and heaters, with acoustic absorbent panels. These temporary structures would not be put in place if they created safety issues related to exhaust vapor build-up. ● When feasible, activities such as helicopter use and blasting, could be scheduled at the same time. These and other important design features should be required. 		Information regarding helicopter use for avalanche control has been included per the response to comment 17634.174.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	359	<p>2. Noise Pollution</p> <p>Increased noise pollution is an expected impact of the proposed Stibnite Gold Project, with both action alternatives creating some short-term periodic noise exceedance impacts at 4 to 5 of the defined noise sensitive receivers in the project area (SDEIS, ES-12). Based on this finding, a suite of mitigation measures should be put in place to minimize noise pollution from SGP activities, including mufflers on construction equipment and drill rigs, scheduling noisy activities concurrently, and turning off noisy equipment when not in use. Furthermore, noise reduction effectiveness monitoring should be implemented to assess if the relevant noise reduction equipment is being used properly and will monitor the effectiveness of the equipment in reducing light and noise levels. The true degree of sound reduction should first be measured with and without the sound baffles before the start of operations.</p> <p>The Forest Service's noise analysis failed to take into account topography or vegetation which can have significant effects on sound propagation: Sound from SGP activities at recreation sites/areas is based on estimated noise that does not consider the effects of topography or vegetation on noise propagation. Therefore, the noise impacts presented in the analysis may be more extensive than would actually occur given the topography and vegetation present in the analysis area." (Recreation Resource Specialist Report, p. 13). 			topography may channel or concentrate sound or in areas with fewer trees and more grassy slopes or talus. We point out that one of the key characteristics of the FCRNRW is “natural-wilderness ecological systems are substantially free from the effects of modern civilization.” The proximity of the FCRNW and the expectation of hearing only natural sounds highlights the importance of a complete analysis.		
Samuel Penney (Chairman)	19396	185	<p>4.6 Noise</p> <p>Tribal concerns regarding noise include noise health stressors affecting wildlife as well as noise impacts to tribal experiences in traditional use areas. The Forest states in the 2020 DEIS that “...noise in a community can contribute to stressors that may influence health such as”:</p> <ul style="list-style-type: none"> • Reductions in quality of life (potentially work, home, and school life), as noise can disrupt speech and sleep, potentially leading to increases in stress and reduction in productivity. • Effects on cardiovascular health via increases in blood pressure. • Changes in hormone levels related to a stress response. 	NOI	<p>The nearest communities (i.e., Yellow Pine, Warm Lake) are located far enough away from the sources of project-related noise that noise levels at those locations would not be increased above the 55 dBA noise threshold and therefore potential noise health stressors are not anticipated.</p> <p>Locations nearer to operations, within 0.78 miles, could experience noise levels above the 55 dBA threshold on temporary short-term bases, typically related to passing road traffic, but due to the short-term nature of these impacts, noise health stressors are not anticipated.</p>

Hazardous Materials

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Elizabeth Barnes	6652	2	p. 2-101 Use of rodenticides is discussed in table 2.4-12 with no description of which types/brands would be used, what quantities, and no assessment whatsoever of the environmental impact of rodenticides to wildlife, no proposed alternative such as integrated pest management, no disposal plan, and no mitigation strategies are presented. Rodenticides are a major cause of wildlife fatalities among mountain lion, owl, hawks, and other predators who endure long and painful deaths after ingesting one or more rodents containing blood coagulants or other lethal chemicals (van den Brink et al. 2018). There is new research to indicate that rodenticides may also pose significant risk to aquatic systems via sewage (Ajo et al. 2018). Rodenticides do not belong in wilderness areas.	HAZ	There are no specific plans at this time for use of rodenticides at the SGP. The inclusion of rodenticides in the subject reference in Table 2.4-12 was simply to call out the applicable Forest Plan standard and indicate it would apply to the SGP.
Steve Hull (Fire Chief, Cascade Rural Fire Protection District)	10178	3	CRFPD is also concerned with the amount of fuel and hazardous materials that is proposed to be hauled to the Stibnite Gold Project. Currently CRFPD does not have the necessary equipment in the event of an accident hauling these materials. CRFPD would also need additional equipment and training to mitigate a hazardous materials incident. However, based upon the information in Section 3.2.5 Material Transportation Safety Measures, I believe Perpetua has done a good job in outlining their standard operating procedures and understand they are in the process of developing similar hazardous materials transport plans. I do appreciate that all transport drivers will be required to have spill response, safety and resource awareness training before being allowed to transport hazardous material on our back country roads. I also appreciate the additional safety measures that will be implemented to reduce the risk of accidents. Perpetua Resources has taken extra safety precautions to date and their safety record is good. It is my job to make sure it remains that way. The CRFPD has had the opportunity for one joint HAZWOPER training session with Perpetua and we look forward to additional joint hazardous materials training opportunities for our team in the future.	HAZ	No further response required. General in nature or position statement.
Kevin Vivian (President, Agri-Service)	14669	5	<p>All of this is being done with the highest standards of worker and environmental safety in mind. Perpetua has a proven track record of success when it comes to safely managing hazardous materials and environmentally sensitive areas, and the Stibnite Gold Project will be no different.</p> <p>The company is planning to construct all the necessary infrastructure to transport and store any hazardous materials involved in the project in a way that prioritizes safety, and the project will include an on-site hazardous materials response team.</p>	HAZ	No further response required. General in nature or position statement.

Lehrer, Laura	16878	3	The actual likelihood of toxic spills and increased traffic along highway 55 and other non-paved routes to and from the mine site are minimized in the SDEIS. According to the analysts of IHESG, " The DEIS states that there will be 12,775-17,885 heavy vehicle trips every year, many loaded with hazardous chemicals (diesel, explosives, sulfuric acid, and sodium cyanide). Transportation routes north and south of Valley County are along major rivers, including the North Fork Payette River and the East Fork of South Fork of the Salmon River. This could potentially be 255,500+ trips on Idaho's 2nd highest year-round road (Hwy 55) over the course of the mine's operation. Even spill risk of .01% would result in at least 25 spills on roads, crossing sixty-nine waterways. These numbers indicate that the impacts that spills and accidents have on the environment and human safety along the transportation corridor should be seriously and thoroughly considered."	HAZ	The transportation of hazardous materials should be taken in context of the existing traffic pattern in the analysis area. Section 4.16 discusses the relative effects of the SGP-related transportation on the different segments of access roads proposed to be used during the construction and operation of the SGP. Table 4.16-2 shows that all traffic related to the SGP operations (the phase involving the most truck deliveries of hazardous materials) would access the site via Cascade and the Warm Lake Road to the SGLF. Data in the table shows that the total increase in all SGP-related traffic in this road segment would have an AADT of 156, which would be a 3.2% increase over baseline conditions on SH 55. Of this total, about 16% (25 AADT) would consist of heavy vehicles, which would include hazardous materials deliveries. This portion of the total AADT would comprise about 0.5% of the SH 55 AADT during operations, which is a relatively small increase. Section 4.7 of the EIS discusses potential effects of spills or hazardous materials. Table 4.7-1 lists the hazardous materials proposed to be used in the 2021 MMP and shows that the largest quantities would be for diesel fuel, gasoline, propane, ammonium nitrate, and sodium cyanide.
Clouser, Ludmila	17581	2	<p>If approved, the Stibnite Gold Project will require large quantities of hazardous materials to be transported to and from and used at the mine site during the 15 years of mining operations (Table ES-1) and, to a larger extent, for as long as water treatment is necessary.</p> <p>Hazardous materials include fuels, explosives, acids, cyanide, ammonium nitrate, lime, antimony concentrate and other toxic substances. All these are highly poisonous to animals and humans. In total, more than 3,000 loads of hazardous materials would be transported to or from the mine every year during operations (Table ES-1). The loads would include more than 8,300,000 gallons of flammable materials (diesel, propane, gasoline) as part of more than 9,400,000 gallons of hazardous bulk liquids to be brought to the mine site annually. In addition, more than 46,000 tons of hazardous bulk solids would be transported to or from the mine site (Table ES-1). This includes the annual use of 4,000 tons of sodium cyanide, which would be delivered in 167 trips carrying 24 tons each, or roughly one trip every other day.</p> <p>Isn't there be a high hazard should a spill happen along HWY55 and extend into the NF Payette River? This high risk obviously exists along mine access roads into the SFSR, Johnson Creek, and EFSF and its tributaries. One spill could kill 100% of the eggs, fry, juveniles, and spawning adults of up to four species of fish to name just one aspect.</p> <p>I ask: Why are there no project-specific spill risk calculations for numbers of spills and spill probability in the SDEIS? (SDEIS 4-345). Why wasn't HWY55 (through Boise, McCall, and New Meadows), nor HWY95 corridor considered in any transportation analysis? The estimated spill rate per truck mile in the SGP SDEIS is many times lower than should be calculated because the "estimated amount of miles traveled" only assumes mileage from the Highway 55/Warm Lake Road junction. Risk extends from the origin of the reagents to the mine and all the way to the final destination. (SDEIS 5-34).</p> <p>This extends to Environmental Impacts. The proposal violates the Payette and Boise Forest Land Resource Management Plans and fails to minimize all adverse environmental impacts, thus violating two federal laws – the Federal Land Policy and Management Act and the Organic Act. The SDEIS also violates the Clean Water Act and conflicts with established Treaty Rights.</p>	HAZ	A revised incident risk analysis for hazardous materials has been added to Section 4.16.2 of the Final EIS. This includes an analysis of longer transportation routes on existing highways than was included in the SDEIS and examines recorded and predicted incident rates along those highways including incidents involving hazardous materials.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	23	The scope of the effects analyses are also geographically limited. For example, as described in Lubetkin (2022), the transport of hazardous materials to the mine site will involve a much larger geographic area than the transportation route identified in the SDEIS. Instead of only considering the transportation corridor from SH-55 at Cascade to the mine site, the true measure of the communities and environment at risk will extend to the distribution points of the reagents brought to the mine and the destinations of the ore concentrate and wastes taken from it. Spills of hazardous materials may have significant impacts to public health and the environment that must be fully analyzed in the SDEIS.	HAZ	A revised incident risk analysis for hazardous materials has been added to Section 4.16.2 of the Final EIS. This includes an analysis of longer transportation routes on existing highways than was included in the SDEIS and examines recorded and predicted incident rates along those highways including incidents involving hazardous materials.

Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	118	The SDEIS makes unjustified conclusions about spill risk The SDEIS states: "It is expected the risk associated with a spill large enough to negatively affect fish or aquatic habitat would generally be low." (SDEIS at 4-333). This unjustified conclusion overlooks inevitable cumulative, chronic, and potentially additive effects of multiple spills over time. It underestimates effects on fish habitats because assessments were based on measuring the amount of stream that is a 91 meter distance from the roadway centerline, which is less than half the published distance for a 200-meter impact zone around rural roadways. The conclusion also estimates spill risk rates that are two orders of magnitude lower than rates cited in other large mine DEIS's.	HAZ	Assuming there would be cumulative and additive effects of multiple spills within the SGP area is an unrealistic condition. Section 4.7.2.2 describes the potential sources of any spills of hazardous materials and the EDFs that are planned to largely contain these spills so they are not released to the environment. Spills that might occur outside of secondary containment would be immediately cleaned up and the contamination properly disposed so the environmental effects would not be cumulative or additive.
Idaho Regulatory Agencies	17718	76	The International Cyanide Management Code (which is always referred to in the abbreviated form "Cyanide Code"). It may be that the association with this voluntary initiative is being misrepresented by Perpetua by stating that "Perpetua Resources has indicated their intent to design and operate the cyanidation facility in compliance with the ICMC." Previously under 2.4.5.7, Perpetua states that it will operate "consistent" with the Cyanide Code. Is Perpetua a signatory to the Cyanide Code? If not, why? And is not being a signatory why you use terms such as "in compliance with"? This suggests that Perpetua will not adhere completely to the Cyanide Code. Correct? It possibly misleads the public into believing adherence, and therefore being a signatory, which commits companies to triennial audits conducted by independent third-party auditors. Companies that adopt the Cyanide Code must have their operations that use, transport, or produce cyanide audited to determine the status of Cyanide Code implementation. Those operations that meet the Cyanide Code requirements are then certified. Will Perpetua seek certification? If not, why? Please consider a rewrite to further explain.	HAZ	Yes, Perpetua would be a signatory and participant in the International Cyanide Management Institute's (ICMI) Cyanide Code voluntary certification program, which promotes and helps ensure the safe and environmentally responsible management of cyanide use within the gold and silver mining industries. To maintain certification, every three years Perpetua would be required to undergo compliance audits conducted by qualified, independent third-party auditors that meet ICMI requirements.
Giles, Robert (Mayor McCall, ID)	17834	6	Next, the Deinhard-Boydston route crosses the North Fork of the Payette River, which is identified by Idaho DEQ as a section 303(d) impaired waterway under the Clean Water Act with multiple TMDL's in effect. Significant investments have been made by the City, the Idaho Fish and Game Department, the Idaho Department of Environment Quality, the Valley County Soil and Water Conservation District, the National Park System, private non-profit groups and individuals to restore its health as an important part of the overall watershed in this area for fish habitat, recreation and downstream water quality of Lake Cascade. The water quality regulations imposed on the North Fork Payette by Idaho DEQ are so strict that even our community's treated wastewater isn't allowed to be discharged into it; 100% of our treated wastewater is land-applied on neighboring farmland. A hazardous spill into this waterway would be potentially devastating reversing years of investments and have downstream impacts on river users and the quality of Lake Cascade.	HAZ	Perpetua will continue to coordinate training opportunities with regional Fire Departments (Yellow Pine, Cascade, Donnelly & McCall); Council, Riggins and New Meadows would be included in future training opportunities. Perpetua Resources anticipates positioning a mixed Hazardous Materials Response Trailer at the Valley County Emergency Operations Center in Cascade, Idaho.
Giles, Robert (Mayor McCall, ID)	17834	9	The City is highly concerned about any hazardous material spills in our jurisdiction and specifically into the North Fork Payette River and the Big Payette Lake. The McCall area fire departments do not have a HazMat Team nor proper materials to respond to, contain or clean up a spill. According to the McCall Fire District Chief the closest HazMat Team is a minimum of four hours away and McCall Fire is only equipped to issue evacuation notices and clear the scene while waiting for a HazMat Team to arrive. Four hours is a substantial amount of time for hazardous materials to spread into the North Fork of the Payette River and into the air over a populated area.	HAZ	Perpetua will continue to coordinate training opportunities with regional Fire Departments (Yellow Pine, Cascade, Donnelly & McCall); Council, Riggins and New Meadows would be included in future training opportunities. Perpetua Resources anticipates positioning a mixed Hazardous Materials Response Trailer at the Valley County Emergency Operations Center in Cascade, Idaho.
Giles, Robert (Mayor McCall, ID)	17834	10	Since mine traffic is forecasted to occur 5 days/week for 20 years across this river crossing, the risk of exposure to an accident is high especially during winter conditions. Although the traffic and transportation plan contemplate that mine-related traffic will primarily use the Deinhard/Boydston corridor, there is no prohibition of such traffic from traveling past Big Payette Lake. Big Payette Lake is McCall's sole source of drinking water. Mine-related traffic through downtown past Big Payette Lake is unacceptable for the sole reason of the catastrophic consequences of a hazmat spill. The City previously commented on the importance of protecting Big Payette Lake in its letter to the Forest Service regarding the DEIS dated October 2020.	HAZ	No further response required. General in nature or position statement. See also the response to comment 17834.9.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Giles, Robert (Mayor McCall, ID)	17834	11	The applicant has demonstrated a willingness to address this type of issue by providing numerous spill kits along roadways such as Johnson Creek Rd to prevent/quickly respond to accidents along the routes into the Stibnite area and along rivers within the project area. The City respectfully requests that the Forest Service include a mitigation measure in a second supplemental DEIS that the same consideration be given to our community and our protected waterways. The Forest Service should require the applicant to provide HazMat response resources in McCall or another nearby location to allow for a timely response. The Preferred Alternative in the SDEIS discusses at length the company's spill protection plan but that is just for the area within the project. It assumes that spills or accidents occurring outside the project area are the responsibility of the carrier and local authorities. If not for the mine project, these hazardous materials would not be coming through our communities and therefore it should be the company's responsibility to ensure that it is not solely the burden of taxpayer funded local agencies to respond to a spill of magnitude.	HAZ	Perpetua has and will continue to offer joint HAZWOPER training and spill response training to all the regional Fire Departments (Yellow Pine, Cascade, Donnelly & McCall). Council, Riggins and New Meadows would be included in future training opportunities. Previously, Yellow Pine and Cascade Fire Departments have taken advantage of this joint training.
Giles, Robert (Mayor McCall, ID)	17834	12	The company's plan includes notifying their own staff of when hazardous materials shipments are scheduled and by what route so as to minimize potential dangers. The City requests that the Forest Service require in a second supplemental DEIS that the company notify local public safety and first responder agencies of scheduled hazardous materials shipments and routes for our situational awareness and preparedness.	HAZ	The 2021 MMP describes the quantities of materials, and anticipated delivery frequency for all materials (hazardous reagents or otherwise) and selected transport routes would be identified by the Forest Service in the final Selected Alternative. All transports under Perpetua's "control" would originate at the Logistics Facility and all deliveries would be required to stop and check in before convoying to the Project site. Perpetua would continue to work with local safety and first responder agencies to define an acceptable method to communicate timing, scheduling and routes for shipments of hazardous materials. We note that this coordination is in process and would continue to be facilitated by Perpetua's Community Partnership Agreements and interactions with community representatives included on the Stibnite Advisory Council.
Giles, Robert (Mayor McCall, ID)	17834	30	The City is highly concerned about any hazardous material spills into the North Fork Payette River. The McCall area fire departments do not have a HazMat Team nor proper materials to respond to, contain or clean up a spill. According to the McCall Fire District Chief the closest HazMat Team is a minimum of four hours away and McCall Fire is only equipped to issue evacuation notices and clear the scene while waiting for a HazMat Team to arrive. Four hours is a substantial amount of time for hazardous materials to spread into the North Fork of the Payette River and into the air over a populated area. Since mine traffic is forecasted to occur 5 days/week for many years across this river crossing, the risk of exposure to an accident is high especially during winter conditions. This is an important impact that should be included in the Final EIS. The applicant has demonstrated a willingness to address this type of issue by providing numerous spill kits along roadways such as Johnson Creek Rd to prevent/quickly respond to accidents along the routes into the Stibnite area and along rivers. The City respectfully requests that the Forest Service include a mitigation measure in the Record of Decision that the same consideration be given to our community and our protected waterways. The Forest Service should require the applicant to provide HazMat response resources in McCall or another nearby location to allow for a timely response. I have attached an email from the McCall Fire Department with recommendations for a HazMat resource and how it could benefit the larger Valley County community.	HAZ	Perpetua will continue to coordinate training opportunities with regional Fire Departments (Yellow Pine, Cascade, Donnelly & McCall); Council, Riggins and New Meadows would be included in future training opportunities. Perpetua anticipates positioning a mixed Hazardous Materials Response Trailer at the Valley County Emergency Operations Center in Cascade, Idaho.
Giles, Robert (Mayor McCall, ID)	17834	32	Summary of impacts City requests be included in the Final EIS The City respectfully requests the Forest Service Identify and analyze impacts to the North Fork Payette River, a 303(d) impaired waterway, from hazardous materials and explosives transported to and from the mine using the Deinhard/Boydston route, including but not limited to, the lack of timely hazardous materials response which will negatively impact human health and the health of other species in the event of an accident.	HAZ	Perpetua will continue to coordinate training opportunities with regional Fire Departments (Yellow Pine, Cascade, Donnelly & McCall); Council, Riggins and New Meadows would be included in future training opportunities. Perpetua anticipates positioning a mixed Hazardous Materials Response Trailer at the Valley County Emergency Operations Center in Cascade, Idaho.
Alan Haslam (Vice President, Permitting, Perpetua)	18649	7	And each day's postponement of the SGP's plan to remove the waste rock and reprocess the ore grade tailings left behind in their unlined state at the Spent Ore Disposal Area is one more day that arsenic will continue to load into Meadow Creek at the rate of approximately 1100 pounds a year.	HAZ	No further response required. General in nature or position statement.

Resources Idaho, Inc.)					
Small, Nathan (Chairman, Fort Hall Business Council, Shoshone-Bannock Tribes)	18903	25	Please explore and re-evaluate any use of Johnson Creek and Stibnite Roads during either construction and/or operation. This reviewer has recently visited the proposed mine site and driven these roads. Risks to the environment from accidental spills, air emissions, and water along these routes are unacceptable.	HAZ	The Johnson Creek road is currently the main access route to the Stibnite site and has been for years. As described in Section 2.4.4.3 of the EIS, until the Burntlog Route is constructed, the Johnson Creek Route would continue to be used to support the construction activities at the SGP. As described in Section 3.7.4.2, supplies, including fuel deliveries, to the Stibnite site have been occurring since 2011 with no recorded spills along the route. The movement of supplies along this route would be improved by the EDFs described in Table 2.4-13 and the practices discussed in the Safety and Emergency Access subsection of Section 4.16.
Small, Nathan (Chairman, Fort Hall Business Council, Shoshone-Bannock Tribes)	18903	39	The Tribes suggest to the USFS that there be no transportation of hazardous waste or hazardous materials to the mine area until the Burnt Log Road is constructed.	HAZ	The Johnson Creek road is currently the main access route to the Stibnite site and has been for years. As described in Section 2.4.4.3 of the EIS, until the Burntlog Route is constructed, the Johnson Creek Route would continue to be used to support the construction activities at the SGP. As described in Section 3.7.4.2, supplies, including fuel deliveries, to the Stibnite site have been occurring since 2011 with no recorded spills along the route. The movement of supplies along this route would be improved by the EDFs described in Table 2.4-13 and the practices discussed in the Safety and Emergency Access subsection of Section 4.16.
Small, Nathan (Chairman, Fort Hall Business Council, Shoshone-Bannock Tribes)	18903	47	Define and identify "appropriate disposal facility". If hazardous waste is expected, then please discuss in more detail.	HAZ	The reference to an appropriate offsite disposal facility is related to the discussion in Section 2.4.5.6 of removal of spent ore and legacy tailings according to the Environmental Legacy Management Plan (Perpetua 2021d). The concern is potentially encountering waste material that is currently unknown and cannot be directly used or reprocessed on site. Such material would be sampled and chemically characterized to determine if it can be handled as solid waste or a waste requiring special handling. The offsite disposal facility would be chosen based on its legal ability to handle the waste characteristics, which is the meaning of this use of the word "appropriate". It would be speculative at this time to be more definitive as to the potential wastes that may be encountered or the offsite disposal facilities that might be utilized.
Joseph Pietri	19062	8	Acid Mine Drainage yet another issue. It is no secret that occurs and accidents happen. Why is AMD not addressed anywhere in the SDEIS? It's existence seems to be ignored. Examples of a few Mining related incident possibilities : A Truck Crash spills more waste from Gold King Mine into Creek-AP July10,2018. Zortman / Landusky Mine Montana Heap Leach Mine, over a dozen Cyanide spills, AMD and an abysmal history. With a bankruptcy leaving a 32 million dollar clean up bill. Mount Polley , Lake Quesnel, Likely, BC, Ca. (Tailings Dam Breach) I'm sure there are many more that can be cited.	HAZ	The presence of AMD in the baseline conditions is discussed in Section 3.9.4 where it is shown that acid rock drainage has not been identified at the site in existing seeps, springs, streams, or groundwater. Data presented in Section 3.9.4.2 related to testing for potential acid generating characteristics shows that the proposed development rock should not be prone to acid generation. Some portions of the ore had more potential for acid generation than the development rock. However, ore mined at the site would be processed through the mill and the tailings eventually disposed of in the lined TSF. Section 4.9.1.1 describes the evaluation of potential leachate water from SGP ore stockpiles, tailings, and development rock and concludes that all these waters would have circum-neutral pHs. The potential for AMD has been evaluated in the EIS and found to not be a problem. The commenter makes references to spills at other mine operations including truck crashes and spills of process waters and tailings. The applicable EDFs for materials handling and the potential for spills of reagents, petroleum products, process water, and tailings is discussed in Sections 3.7 and 4.7 of the EIS.
Joseph Pietri	19062	11	Where is Perpetua's responsibility when a hazardous material truck dumps its load say on Goose Creek Grade? or other hazardous road stretches between the mine and destination	HAZ	Perpetua has committed to responding to spills and emergencies (associated with its Project traffic) starting at the Warm Lake Road and SH 55 intersection all the way out to the Project site. Before this point, it is the responsibility of the transport company, just like all other hazardous materials loads, or nonhazardous materials loads currently traveling throughout Idaho, to respond to and clean up, or contract out cleanup services in the event of an accident or spill.
Karen Balch (North Fork Veterinary Service)	19228	5	Pollution of any sort degrades nature. As a veterinarian, I have unique working knowledge of biological processes across species, including various disease etiologies (or causes) that can present in various diseases. I have professionally investigated real and potential poisoning of domestic animals. With warmer temperatures, we are seeing more cyanobacteria in water bodies that can kill animals quickly by	HAZ	The EIS has evaluated the types of pollution concerns raised by the comment. Section 4.5 of the EIS discusses geochemistry of the soils and reclamation cover materials to be used to reclaim the proposed mining disturbances. Section 4.7 of the EIS discusses the potential environmental impacts of handling and transportation of hazardous materials. Section 4.9 of

			<p>neurotoxins that have no reversal. I am particularly concerned about “emerging diseases” and zoonotic diseases (diseases that are transmissible between animals and humans). Causes of zoonotic diseases may be fungal, bacterial, viral, endo- or ectoparasitic, infectious, or toxicosis, such as those caused by heavy metals. Currently, bald eagles are dying of lead toxicosis that is excruciatingly painful. In 2017, the Asian Longhorned tick was discovered in the US and is spreading rapidly indicating yet another vector-borne tick on the radar. The impact of human activities year-round with transportation of potentially lethal chemicals inevitably will have an impact on wildlife but I do not believe that exactly how is fully understood.</p> <p>Notably, the level of heavy-metal toxicity associated with historic mining at the Stibnite site is sufficient that the EPA proposed Stibnite as a Superfund site on the National Priorities list in 2001 and a remedial investigation started in 2002.</p>		the EIS discusses the potential environmental impacts on surface water and groundwater quality including all regulated metals and other pollutants. The CERCLA history of the site and immediate response to the CERCLA concerns raised by the commenter is discussed in Section 1.3 of the EIS. Sections 4.12 and 4.13 of the EIS discusses potential environmental impacts to fish and terrestrial wildlife. Responses to the concerns identified in the CERCLA investigations of the property as parts of the 2021 MMP are addressed in Sections 2.4.5, 2.4.7, and 2.4.8 of the EIS.
Olin Balch (North Fork Veterinary Service)	19234	3	<p>Pollution of any sort degrades nature. As a veterinarian – the very definition of a practical biologist, I have unique working knowledge of biological processes across species and have professionally investigated real and potential poisoning of domestic animals. Notably, the level of heavy-metal toxicity associated with historic mining at the Stibnite site is sufficient that the EPA proposed Stibnite as a Superfund site on the National Priorities list in 2001 and a remedial investigation started in 2002.</p> <p>In 2019, the US Department of the Interior and US Geological Survey completed the scientific investigations report titled “Arsenic, Antimony, Mercury, and Water Streams near Stibnite Mining Area, Central Idaho, 2011-17.” In short, this study documents altered stream configuration and habitat in the study area. Dangerous toxin levels for aquatic, avian, non-human mammalian, and human life are directly associated with documented levels of arsenic, free cyanide, lead, mercury, silver, and zinc, and antimony. Even this most recent USGS study, many years after the most recent active mining activity in the Stibnite area ceased, identified harmful levels of arsenic, antimony, and mercury contamination in those local waterways. As a veterinarian, I find this profoundly troubling and indicative of the on-going damage associated particularly with large scale mining, whether historical or contemporary.</p>	HAZ	The EIS has evaluated the types of pollution concerns raised by the comment. Section 4.5 of the EIS discusses geochemistry of the soils and reclamation cover materials to be used to reclaim the proposed mining disturbances. Section 4.7 of the EIS discusses the potential environmental impacts of handling and transportation of hazardous materials. Section 4.9 of the EIS discusses the potential environmental impacts on surface water and groundwater quality including all regulated metals and other pollutants. The CERCLA history of the site and immediate response to the CERCLA concerns raised by the commenter is discussed in Section 1.3 of the EIS. Sections 4.12 and 4.13 of the EIS discusses potential environmental impacts to fish and terrestrial wildlife. Responses to the concerns identified in the CERCLA investigations of the property as parts of the 2021 MMP are addressed in Sections 2.4.5, 2.4.7, and 2.4.8 of the EIS.
Joel Drake	19251	4	<p>Permanently-placed Enhanced Spill Kits at Key Points along the Landmark Grade section of Warm Lake Highway The Plan calls for pilot cars and spill response units to accompany each transport of liquid hazardous materials, but that is not enough. Due to the incline of the Landmark Grade section of Warm Lake Highway and its proximity to the creek, any spilled liquids will quickly drain into and immediately contaminate Warm Lake Creek (ergo, Warm Lake itself). For this reason, extra resources are needed to effectively respond to spills on this section of the transportation route. Permanently-placed spill response kits with sufficient capacity and enhanced capabilities are needed to respond and contain spills up to 10,000 gallons in volume on this section of road.</p> <p>The Plan and Draft EIS need to be revised to acknowledge the need for and describe the planned placement of enhanced spill kits at key points along the Landmark Grade section of Warm Lake Highway.</p> <p>Any Special Use permit issued by the Forest Service for transportation of materials to and from the mine site must specifically require the permanent placement of enhanced spill kits at key points along the Landmark Grade section of Warm Lake Highway.</p> <p>Any permit issued to Perpetua Resources by the IDEQ (Idaho Department of Environmental Quality) concerning water quality and spill mitigation measures must require the permanent placement of enhanced spill kits at key points along the Landmark Grade section of Warm Lake Highway.</p>	HAZ	Perpetua feels placing a dedicated spill kit at this location is unnecessary as this type of spill response equipment and response capacity would already be contained in a response trailer that would be accompanying, and traveling downstream of (i.e., trailing behind the convoy), all hazardous material convoys entering the Project site. The downstream placement and the fact that the response equipment would be traveling with appropriate spill response materials places it in the optimal location to be effective in responding to emergency situations and in the event of a spill.
Joel Drake	19251	10	<p>Spills of Fuel and Liquid Hazardous Materials - Magnified Risk Along a Treacherous Stretch of Road The remote location of the proposed mining site relies on extremely heavy, unprecedented use of transportation infrastructure corridor (roads and bridges) in the National Forest System (NFS). In many sections of the corridor, the road’s alignment and configuration are not designed or constructed to accommodate the proposed level of use or prevent hazardous material spills from immediately flowing to fragile, pristine waterways which flow into Warm Lake and then to the South Fork of the Salmon River.</p>	HAZ	No further response required. General in nature or position statement.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			Under the Plan, ALL materials and supplies transported to the site and ALL minerals and antimony concentrate extracted from the site would be transported through a single treacherous and regionally notorious 5-mile segment of Warm Lake Road - from Warm Lake to the Landmark summit (Valley County road #10-579).		
Joel Drake	19251	12	Given the Plan's projected volume of liquid hazardous material runs, the road's condition and configuration, and harsh weather conditions during much of the year, spill events are inevitable. The Plan and SDEIS do not even quantify the spill risk over the transportation route, which is common practice. Other similar proposals have included calculated spill risks. Why has Perpetua elected to omit project-specific spill risk calculations in the Plan and this SDEIS?	HAZ	A revised incident risk analysis for hazardous materials has been added to Section 4.16.2 of the Final EIS. This includes an analysis of longer transportation routes on existing highways than was included in the SDEIS and examines recorded and predicted incident rates along those highways including incidents involving hazardous materials.
Joel Drake	19251	14	During the Plan's proposed period of operations, approximately 11,000 truckloads carrying environmentally hazardous liquids would navigate through the precarious 5.1 mile section of transportation corridor described in pages 3 through 6. Within the Plan, Perpetua discloses that fact that they experienced a reportable spill in 2012. They do not specify what substance was spilled. Given the much lower volume of transports conducted prior to and since that date, the incident reported in 2012 represents a spill rate per delivery much greater than 1/11,000. Given the high volume of proposed delivery instances which would occur during all weather and road conditions over the course of each year, one or more catastrophic spills of liquids damaging to water quality are inevitable. As noted earlier, spills within the constricted canyon would rapidly flow to Warm Lake and then to the S. Fork of the Salmon River.	HAZ	It is incorrect that the 2012 spill was related to transportation of hazardous materials by truck. The 2012 spill is described as a diesel spill resulting from an airplane crash. It was cleaned up and no further action was required. There have been no spills of hazardous materials from truck transport related to the Stibnite activities. It is also incorrect that hazardous materials deliveries would occur during all weather and road conditions. The Transportation of Hazardous Materials subsection of Section 4.7.2.2 describes the EDFs and practices that would be employed to reduce the potential for releases of hazardous materials, including considerations of weather and road conditions that would impact safe use of the access roads.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	604	"Hazardous Materials: Bounded by the bordering transportation routes that would provide access to the mine site." This figure has "Roads, Disturbance Areas, Underground Workings, and Patented Claims". It does not indicate any area bounded by the bordering routes. Please revise figure.	HAZ	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	605	"Hazardous Materials: SGP components including the mine site and access roads." Not included in the CEA description in Section 5.7. Please add.	HAZ	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	640	"The CEA for hazardous materials is bound by the bordering transportation routes that would provide access to the SGP ." This does not match Table 5.1-1 - please reconcile.	HAZ	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	641	"The SGP has included transportation of fuel (diesel, gasoline, and jet fuel) to the mine site. This activity occurs on existing County and Forest Service roads ." Please delete or clarify rationale for including this in the absence of spills with persistent impacts.	HAZ	The bulleted list in Section 5.7.2 does not describe impacts of hazardous materials but is intended to describe past and present actions that involve hazardous materials.
Alan Haslam (Vice President, Permitting, Perpetua	19325	642	"however, this project would involve 10,600 acres of treatment over a short period of time, such that the contribution of the action alternatives combined with this, and other similar projects would result in negligible changes to the overall traffic volume ." This conclusion sentence is about overall traffic volume but this section is about Hazardous Materials. Please conclude about Hazardous Materials or make clear connection to Hazardous Materials.	HAZ	Edit has been made.

Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	250	"Perpetua has prepared written spill response procedures described in their SGP Emergency Response Program (OHS-008) and SPCC Plan (OHSF-008K) that include: " The SPCC plan is ESOP-028 . OHS-008 is the number of the form for spill response in the ERP. Please replace " OHS-008 " with " ESOP-028 ."	HAZ	ESOP—028 is the formal Spill Prevention Control and Countermeasure Plan as regulated by federal code. OHS-008 (Emergency Response Program) and OHSF-008-K (Spill Emergency Response Plan) and associated documents work in concert with ESOP-028 and are the governing documents related to emergency response and spill response. The documents will crosswalk a little better following the annual update of ESOP-028.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	251	" <i>Though the Burntlog Route includes a greater number of stream crossings</i> " According to the numbers in the same paragraph, the Johnson Creek route has more stream crossings. Please revise.	HAZ	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	252	" <i>Mine transport begins on Warm Lake Road (CR 10-579) where the risk of spills would be lower, as it is paved and maintained by Valley County and has overall gentler grades with the exception of Big Creek Summit</i> ." Incorrect. Please replace " Big Creek Summit " with " Warm Lake Summit "	HAZ	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	10	Comments on applicable SDEIS sections include minimal technical clarifications for Section 4.7 only.	HAZ	No further response required. General in nature or position statement.
Siegel	19355	3	I have questions concerning the transportation of materials and waste. The northerly route coming through McCall requires analysis and identification of impacts. There will be 20 years of continuous traffic impacts through this corridor which should not have been ignored. The estimated spill rate per truck mile in the SGP SDEIS was 100 times lower than would normally be calculated because the estimated number of miles traveled only assumed those miles are from the State Highway 55/Warm Lake Road junction. Why are there no project-specific spill risk calculations for numbers of spills, and spill probability, in the SDEIS? (SDEIS 4-345) According to SDEIS 5-34 risks extend "from the origin of the reagents, to the mine, and to the destination of the wastes taken away."	HAZ	A revised incident risk analysis for hazardous materials has been added to Section 4.16.2 of the Final EIS. This includes an analysis of longer transportation routes on existing highways than was included in the SDEIS and examines recorded and predicted incident rates along those highways including incidents involving hazardous materials.
Ruth Lewinski	19378	7	3.0 Transport and Traffic Volume Traffic along the Warm Lake Highway, north of Cascade is currently used by residents of the area and for recreational activities. Recreational activities are a primary economic income for the entire region of Valley County. Additionally, proposed transport routes along highway 55, both north and south, are along river corridors. Below are several quotes from the SDEIS: "Current access roads used for the transport of hazardous materials to the mine site include Warm Lake Road (CR 10-579) from Cascade, continuing to Landmark and then on Johnson Creek Road (CR 10-413) to the village of Yellow Pine and Stibnite Road (CR 50-412) to the mine site." (P. 3-99). "The estimated annual average traffic to the SGLF and from the SGLF to the SGP during mining and ore processing operations is also provided in Table 2.4-2. Supplies and deliveries for the SGP during operations would access the SGLF using SH 55 to Warm Lake Road. Approximately two-thirds of all mine-related traffic would originate south of Warm Lake Road and would use SH 55 through Cascade and other communities along SH 55 south of Cascade including Smith's Ferry, Banks and Horseshoe Bend. 8 Approximately one-third of all mine-related traffic	HAZ	No further response required. General in nature or position statement.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			originating north of Warm Lake Road would use SH 55 through the communities of Donnelly, Lake Fork, McCall, and New Meadows", (P.2-22). "In the event a release was to occur, it would likely be relatively small in volume based on estimated container volumes and would be addressed promptly as per the SPCC Plan and Spill Response Plan. The SPCC Plan would address site-specific spill prevention measures, fuel haul guidelines, fuel unloading procedures, inspections, secondary containment of all on-site fuel storage tanks, and staff training." "In the event that large quantities of hazardous materials are spilled into the environment from a transportation incident, or in the event that a spill is not immediately discovered or addressed, the impact could be more substantial." (P. 4-522).		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	151	<p>J. Transportation and hazardous spill risk The following is the Executive Summary from Susan Lubetkin's 2022 analysis of spill risks related to the Stibnite Gold Project SDEIS (included in the attachments): If approved, the Stibnite Gold Project (SGP) will require large quantities of hazardous materials to be transported to and from and used at the mine site during the 15 years of mining operations (Table ES-1) and, to a more limited extent, for as long as water treatment is necessary. In total, more than 3,000 loads of hazardous materials would be transported to or from the mine every year during operations (Table ES-1). The loads would include more than 8,300,000 gallons of flammable materials (diesel, propane, gasoline) as part of more than 9,400,000 gallons of hazardous bulk liquids to be brought to the mine site annually. In addition, more than 46,000 tons of hazardous bulk solids would be transported to or from the mine site (Table ES-1). This includes the annual use of 4,000 tons of sodium cyanide, which would be delivered in 167 trips carrying 24 tons each, or roughly one trip every other day.</p> <p>The Supplemental Draft Environmental Impact Statement (SDEIS) acknowledged the spills can be harmful and that a Spill Prevention Control and Countermeasures Plan (SPCC) would be developed for the proposed SGP (USFS 2022).The discussion of spill risk was largely limited to the transportation corridor, specifically from the junction of SH-55 with Warm Lake Road to the proposed mine site 70 miles away along two different Action Alternative routes, the Burntlog Route and the Johnson Creek Route. The metrics the SDEIS used for assessing spill risk along the transportation corridor were the quantities of hazardous materials to be transported, used, and stored, and the amount of traffic, as well as descriptions of storage practices and a comparison of the characteristics of the two proposed routes (USFS 2022, p. 4-119). Overall, the assessment of spill risks in the SDEIS suffered from several flaws and presented an incomplete picture of the potential impacts from spills.</p> <p>First, Perpetua held up their current track record on the mine access roads as an indication that spills will not be an issue in the future. The SDEIS reported that in 288 trips with fuel tankers carrying 4,000 to 4,500 gallons in the last 11 years, there have been no spills (USFS 2022, p. 3-99). Those 288 trips over more than a decade are roughly the same number of trips that would be needed to transport hazardous materials into and out of the mine site every month during 15 years of operations (3,337 trips per year/12 months per year = 278 trips per month).</p>	HAZ	A discussion of quantitative risk of spills has been added to Section 4.7.2 of the Final EIS.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	152	<p>Second, no quantitative estimates of the numbers of spills that might occur during the lifetime of the SGP were included in the SDEIS, from transportation or from any other causes. Transporting hazardous materials in trucks is a common occurrence in the United States, and there are several governmental agencies that track what is shipped, how far hazardous materials move, and the safety associated with those shipments. In addition, quantitative risk assessment for the transportation of hazardous materials is an active area of study in the operations research branch of applied mathematics. EISs for other mines and resource extraction projects have included calculations for the expected numbers of hazardous materials spills and the probability of at least one spill. The simple model most often used in other EISs is $N = RT$, where N = the expected number of releases of hazardous materials, R = the release rate per mile traveled by a truck carrying hazardous materials, T = the total number of miles traveled by trucks carrying hazardous materials.</p> <p>This model has precedent of being used in other mining EISs and is intuitive: The more miles traveled by trucks carrying hazardous materials, the higher the expected number of spills.</p>	HAZ	A discussion of quantitative risk of spills has been added to Section 4.7.2 of the Final EIS.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	153	Third, the estimated spill rate per truck mile in the SGP SDEIS was 100 times lower than it should have been. The SGP SDEIS calculated (but did not use) their own estimate of R (USFS 2022). The SGP misused Federal Motor Carrier Safety Administration (FMCSA) data to estimate hazardous material spill rates of 1.4×10^{-9} spills per truck-mile in 2013 and 1.9×10^{-9} spills per truck-mile in 2016. Due to a fundamental math error, these estimates are two orders of magnitude too low. By recreating the math performed in the SGP SDEIS and correcting it, an average spill rate of $R_{spill} = 1.814 \times 10^{-7}$ spills per truck-mile for the period of 2009-2019 based on data from the FMCSA is found. Using the same principles and data, one can also calculate the rate of accidents for trucks carrying hazardous materials as $R_{accident} = 1.34 \times 10^{-6}$ accidents per truck-mile. In doing so, the value of R_{spill} calculated is closer to rates cited in other EISs, including for Pogo Mine, which used an estimate of 1.9×10^{-7} spills per truck-mile, and Pebble Mine, which used an estimate of 2.0×10^{-7} spills per truck-mile for diesel spills >3,000 gallons and 7.8×10^{-7} spills per truck-mile for ore concentrate. This adjusted R_{spill} estimate is lower than the rate from the Pipeline and Hazardous Materials Safety Administration, which estimated that there were an average 3.2×10^{-7} spills of hazardous material per truck-mile (Battelle 2001). (Due to underreporting, it is likely that all these estimated rates are too low, perhaps by as much as a factor of ten (PHMSA 2010).)	HAZ	A discussion of quantitative risk of spills has been added to Section 4.7.2 of the Final EIS.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	154	Fourth, Cascade, Idaho, is not a hub of industrial chemical manufacturing and storage. Therefore, the mine supplies would have to come from other locations. Examining potential distributor locations nearest to Cascade for 22 supplies that would be used at SGP (Lubetkin 2022 Table ES-2). Only six supplies (propane, gasoline, nitric acid, sulfuric acid, hydrogen peroxide, and liquid carbon dioxide) were available in the quantities needed for industrial uses within 100 miles of Cascade. Diesel fuel was available inside a 250-mile radius. For the remaining reagents, distributors were only available from cities that were up 500 or 1,000 miles away. Supplies would travel on SH-55 both north and south of Cascade and could potentially impact any of the communities and environments they pass through. Instead of only considering the transportation corridor from SH-55 at Cascade to the mine site, the true measure of the communities and environment at risk will extend to the distribution points of the reagents brought to the mine and the destinations of the ore concentrate and wastes taken from it (Lubetkin 2022 Table ES-2). The overall exposure will depend on the distances the reagents, products, and wastes need to travel and the number of trips that are necessary for the respective quantities of the hazardous materials. The estimated total miles per year using an average value for the road miles for the two action alternatives from Cascade to the mine site and an educated approximation of the minimum distances for sourcing the reagents. For simplicity, one can use the distance to Boise, Idaho, for all the supplies. This set of origin and destination cities is only an example and likely underestimates the total truck-mile exposure per year because both the number of trips and the number of miles to travel used may be lower than the actual values. Using the total number of heavy vehicles trips with hazardous materials, the expected number of spills and crashes along the SH-55 to mine site portion of the transportation corridor (3,503,850 miles over 15 years) and the full distribution points to mine site distance (at least 14,678,325 miles over 15 years) based on the $N = RT$ model and the probabilities of spills and crashes using a Poisson distribution (Table ES-3). Based on that model, there is a 47% chance of at least one spill from a heavy vehicle loaded with hazardous materials between SH-55 at Cascade and the SGP mine site, and a 93% chance of at least one such incident over the full transportation corridor length. Similarly, there are 4-5 accidents involving heavy vehicles laden with hazardous materials expected along the transportation corridor length considered in the SGP SDEIS and 19-20 accidents along the full transportation corridor. The calculations shown here serve as examples of the general process for estimating spill and crash numbers and likely underestimate the risks. Still, these numbers indicate that the impacts that spills and accidents may have on the environment and human safety along the transportation corridor should be seriously and thoroughly considered. (Table in comment submitted)	HAZ	A revised incident risk analysis for hazardous materials has been added to Section 4.16.2 of the Final EIS. This includes an analysis of longer transportation routes on existing highways than was included in the SDEIS and examines recorded and predicted incident rates along those highways including incidents involving hazardous materials.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>According to Mary Faurot (personal communication), when asked at a December 6, 2022, community meeting why the SDEIS only considered the distance between SH-55 and the mine site, “Kevin Kneseck (deputy Forest Supervisor) said that the research showed most spills happen on back country roads, so that’s where they did their ‘analysis’.” Terminating the consideration of spill risks at the junction of Warm Lake Road and SH-55 underestimates the risks of transportation spills in two ways: first, as shown above, it dramatically underestimates the length of the transportation corridor and thus the total number of miles over which hazardous materials would be trucked. Second, the R spill used in the calculations is based on national data, which do not capture the specific hazards associated with different portions of the full transportation corridor. Estimates of spill risk per truck-mile based on data collected nationwide are generalized and miss factors that may be relevant to individual hazardous material transportation scenarios. Some risks are dependent on the route chosen (road grade, number of lanes, weather, etc.) and some are route independent (driver experience level, material type, truck configuration, etc.). SGP would have some significant risks (road grade and quality, avalanche/landslide/rockfall, fires, etc.) that would be expected to increase the spill rate if a detailed model were used. While road improvement and speed limits might help abate some of the risks inherent in the analysis area, it is clear that developing a project-specific spill risk per truck-mile for one or more segments of the transportation corridor would likely result in an estimated rate that is higher than national average spill rate per truck-mile.</p> <p>Both the road-specific spill rates and the lengths of the road associated with each rate are important. Consider an analogy: If a pulmonologist knew that a person smoked both a relatively small number of unfiltered cigarettes (spill risk on back country roads) and a much higher number of filtered cigarettes (spill risk on highways), the doctor would not base their estimation of whether the person is likely to develop lung (or other) cancer only on the number of unfiltered cigarettes, much less by assessing the unfiltered cigarettes as having the same hazard level as filtered cigarettes and ignoring the additional risk posed by the filtered cigarettes. In the case of the SGP SDEIS, the Rspill from SH-55 to the mine site is likely much too low, and the value for T also underrepresented the true transportation corridor. The risk of hazardous material spills from truck traffic related to the proposed SGP is therefore dramatically underestimated.</p>		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	155	The SGP SDEIS described some mitigating procedures to minimize spill risk associated with the transportation of hazardous materials, such as speed limits and having pilot vehicles accompany convoys of heavy trucks (USFS 2022), but questions remain. For example, what would the spacing of vehicles in convoys be? Would there be an upper limit to the number of vehicles in a convoy? If weather or other natural events make a given route impassable, where and how will vehicles with hazardous materials either wait out the event or temporarily store their cargo?	HAZ	The requested information has been added to the Transportation of Hazardous Materials subsection of Section 4.7.2.2 of the Final EIS.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	156	<p>The SGP SDEIS’s rudimentary attempt at describing the risk of hazardous materials spills was constrained to a limited analysis area and a single source (trucks) of potential spills. This narrow consideration of the possible impacts of the transportation corridor and hazardous materials misses other effects related both to the proposed routes and the possibility of spills from other sources. Transportation impacts extend beyond the risk of spills. The physical structure, use, and maintenance of roads may have effects on fish habitats within a 200 meter impact zone from the centerline of rural roadways (Kravitz and Blair 2019). Other environmental effects to consider are greenhouse gas emissions and dust generation, which will be dependent on the amount of traffic and application of chemicals to the roadway. Therefore, the conclusions in the SDEIS that construction of and/or use of the roadways will have limited if any impacts on fish and the aquatic environment are not justified. Safety is also a concern with accidents, injuries, and fatalities all possible along the SGP transportation corridor.</p> <p>Similarly, conclusions that spills will be rare or small are also unjustified. Mine-related spills of hazardous materials can come from many processes besides transportation. The SDEIS did not examine the probability or potential sizes of spills of either tailings or contact water from pipelines or from mining equipment leaks or mechanical failures. Spills from SPCC facilities may be twice as likely as spills from vehicles (Etkin 2006), but the SGP SDEIS did not discuss the possibility of spills from storage facilities. Even if the modeling had been better done, it is likely that the number of spills that</p>	HAZ	<p>The Final EIS examines a broader geographic area for spill risk.</p> <p>Mine-site related spills are described in SDEIS Sections 4.7.2.2 and 4.9.2.2. The disposal of materials following clean-up of spills is addressed in SDEIS Chapter 2 that describes waste management and disposal of hazardous materials in permitted off-site disposal facilities.</p>

			<p>would occur would be much higher than the predictions. As shown in a retrospective analysis comparing the spill risks considered in five Alaska mining EISs and their spill records after years of operations (ADEC 2021), the actual number of spills from trucking accidents is much larger than the N = RT model would predict (Lubetkin 2022). (The five mines studied had shorter transportation corridors than described in the SGP SDEIS). The proposed SGP amounts of ore processed per day, annual trips hauling hazardous materials, years of operations, and total miles traveled with hazardous materials all fell within the bounds of the five mines' characteristics. For example, the SGP would be second only to Fort Knox/True North in its daily ore processing (20,000 to 25,000 tons per day at SGP compared to 36,000 tons per day at Fort Knox/True North). Further, the combined 114 spills resulting from truck accidents (rollovers and collisions) are only a small subset of the number of spills attributed to all transportation-related releases, such as leaks, unsecured cargo, overfilling, and human error (1,004 spills). Finally, transportation-related spills are in turn only a small subset of the total number of spills that occur associated with mine operations (8,157 spills recorded across the five mines from 1995-2020)(Table ES-4).</p> <p>Spills are not only common but can also be quite large. Four of the five large mines studied had at least eight releases of more than 1,000 gallons or more than 1,000 pounds of hazardous materials (Lubetkin 2022 Table ES-5). Seventy-five percent of the spill incidents at all five large mines involved non-crude oil, but non-crude oil spills only accounted for 5.2% of the volume spilled (Lubetkin 2022). Most of the spill volume was from releases of hazardous substances (e.g. ore concentrate) and process water, which together represented 94.7% of the volume released, even if they were only 24% of the number of incidents (Lubetkin 2022).</p> <p>(TABLE in comment submittal)</p> <p>(TABLE in comment submittal)</p> <p>Overall, the analysis of the potential impacts from hazardous materials in the SGP SDEIS is inadequate to make an informed decision because it is incomplete and does not offer a way to compare the Action Alternatives against the No Action Alternative. EISs for other mines include expected spill numbers and probabilities, the SGP SDEIS did not. EISs for other mines include spill risk rates that are on the order of 2.0×10^{-7} spills per truck-mile, but the SGP SDEIS estimated a spill rate ranging from $1.4-1.9 \times 10^{-9}$ spills per truck-mile, which is two orders of magnitude lower than rates published in multiple sources. The transportation corridor analysis area did not consider any risks beyond Cascade, Idaho. Using a spill risk rate of 1.814×10^{-7} spills per truck-mile based on FMCSA data from 2009-2019, found the probabilities of spills and accidents for the Action Alternatives for the analysis area considered in the SGP SDEIS and the full length of the transportation corridor. The spill rate used is likely too small as it is an average based on national spill data that may suffer from substantial underreporting and the road characteristics near the proposed SGP would increase spill risks. Without an accurate characterization of the true exposure along the transportation corridor and the spill rate per truck-mile, it is impossible to then make informed statements about spill likelihood and the potential consequences to the environment and to public safety from truck accidents alone, much less any of the other potential sources and causes of spills. Data from five other large operational mines illustrate that hazardous materials spills are frequent, can be sizable, and that transportation spills are only a small fraction of mine-related spills.</p> <p>In short, realistic approach to discussing spill risk would</p> <ul style="list-style-type: none"> ● Include all the hazardous materials being transported (not just diesel or other individual hazardous materials) ● Represent the entire length of the transportation corridor ● Use the correct values for Rspill, possibly by including specific values for different stretches of road with different characteristics ● Recognize the N = RT model is too simplistic and investigate the many models that are part of the operations research literature about optimizing the transportation of hazardous materials which would better the highlight the trade-offs in choosing between the Burntlog Route or Johnson Creek Route or the

			<p>No Action Alternative</p> <ul style="list-style-type: none"> ● Recognize that transportation spills do not just come from truck rollovers and collisions ● Recognize that transportation spills are only a small fraction of the total number of spills at mines; pipelines, storage facilities, and mining equipment can also fail, leak, or otherwise have accidental releases of hazardous materials ● Acknowledge that even if spills at mine sites and elsewhere are contained and cleaned up, that process can also create hazardous waste or other impacts that will then have to be dealt with. State quantitatively the minimum number and probabilities of expected spills from all mine-related sources, including any “over the fence” infrastructure, as well as explanation of why such an estimate is a lower boundary, for the Action Alternatives and the No Action Alternative. <p>Finally, if the SGP does go forward, in the interest of keeping the communities informed, the USFS should consider requiring that all spills above a certain threshold be recorded in an up-to-date and publicly available database. The Alaska Department of Environmental Conservation Statewide oil and hazardous substance spills database¹⁸⁴ would serve as a good model.</p>		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	157	<p>As noted by Lubetkin’s Executive Summary above, the Forest Service needs to do more to avoid, minimize and mitigate the risks of hazardous materials spills and to disclose these risks to the public. The environmental effects of a fuel spill on fisheries could be devastating:</p> <p>On September 6, 1989, fuel oil was spilled into Johnson Creek, a SFSR tributary downstream of the project area. Monitoring results indicate a significant reduction in macroinvertebrate populations for 5 miles downstream of the spill site (Newberry 1991). This illustrates that it is reasonable to assume there is a risk of toxic spills that may impact aquatic resources.</p> <p>It is our interpretation that the controlling document for fuel haul along the South Fork Salmon River is still the July 1990 South Fork Salmon River Road EIS (File Reference: EM.11.0006) which placed strict limits on fuel transportation down this road:</p> <p>Hauling of toxic materials, as defined in the Payette National Forest Plan, page IV-238, will be stringently restricted.</p> <p>And</p> <p>Protection of the South Fork from toxic spills will be accomplished by prohibiting hauling of toxic materials, by both commercial and noncommercial users on the South Fork Salmon River Road. Exception can be made for supply of the Reed Ranch and Krassel Guard Station, or emergency situations, with proper safeguards. Criteria for permitting exceptions are presented in Appendix E to the Final EIS.</p> <p>While fuel haul has not been totally banned, the restrictions are severe:</p> <p>No hazardous materials (refer to page IV-238 definition in the Payette National Forest Land and Resource Management Plan) except lime and petroleum products will be transported over the South Fork Road. The basic intent is to eliminate all fuel and other hazardous material haul on the South Fork road unless absolutely necessary.</p> <p>The Forest Service went on to define the requirements for fuel transportation, which include the following:</p> <ol style="list-style-type: none"> 1. Provide for use on a case-by-case permitted basis (District Ranger authority). 2. Considerations in permit issuance are: <ol style="list-style-type: none"> a. For emergency use or to serve South Fork uses only b. Other routes available c. Weather 	HAZ	<p>The 2021 MMP describes the quantities of materials, and anticipated delivery frequency for all materials (hazardous reagents or otherwise) and selected transport routes would be identified by Forest Service in the final Selected Alternative. All transports under Perpetua’s “control” would originate at the Logistics Facility and all deliveries would be required to stop and check in before convoying to the Project site. Perpetua would continue to work with local safety and first responder agencies to define an acceptable method to communicate timing, scheduling and routes for shipments of hazardous materials. We note that this coordination is in process and will continue to be facilitated by Perpetua’s Community Partnership Agreements and interactions with community representatives included on the Stibnite Advisory Council.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>d. Use levels by recreational traffic 3. Maximum fuel at one time is 500 gallons. Fuel must be carried in a DOT approved flammable fuel container. 4. A bond with a value commensurate to the risk involved will be required -Salmon River Road EIS, p. E-2.</p> <p>As such, the 1993 Biological Opinion for the South Fork Salmon River Road contains no provisions allowing for a fuel spill: “...For both short-term construction activities and long-term increase in vehicular traffic, the allowable incidental take due to toxic spills is set at zero.” This Biological Opinion is still in effect as Payette Forest Plan Standard TEST02 states: For Forest-wide, watershed, or project-level Biological Opinions (BOs) and Biological Assessments (BAs) with letters of concurrence, requirements shall continue to apply until their expiration date unless these documents are specifically updated during further review with related regulatory agencies.</p> <p>Following the South Fork Salmon River Road ROD, fuel transportation for mineral exploration and development activities in the general area was specifically restricted along the South Fork Salmon River Road. The Forest Plan was subsequently amended on August 2, 1995 and further fuel-related restrictions were implemented:</p> <p>The Payette National Forest Land and Resource Management Plan limits all hazardous material, except lime and petroleum products, from commercial transport over the SFSR road. The intent is to limit the transport of all hazardous substances over the SFSR road except those that are absolutely necessary (Payette National Forest 1990). Emphasis added. Highlighting the sensitivity regarding fuel haul, the Forest Plan was subsequently amended on August 2, 1995 and further fuel-related restrictions were implemented: 1. Amend Appendix E of the FEIS for South. Fork Salmon River Road Project to include no non-commercial haul of petroleum products in excess of 60 gallons without a permit. 2. Implement a new road closure order that prohibits "Using the road with a vehicle that has a cargo containing more than 60 gallons of petroleum products without a road use permit". Although the subsequent 2003 Forest Plan is silent on this issue, the project-level Biological Opinion for the South Fork Salmon River Road is still in effect and does not allow for any incidental takes for toxic spills into that waterway. The South Fork Salmon River Road EIS also states the following: “Activities reasonably expected to occur within the next 10-15 years were identified and included in the cumulative effects analysis. Unforeseen activities will be analyzed for Forest Plan compliance and cumulative effects when proposed.” (emphasis added). All other recent projects have been consistent with the 1990 South Fork Salmon River Road EIS, including the Hamilton Bar/Three Mile Road closure, the reconstruction of the Goat Creek culvert, the South Fork Restoration and Access Management Plan, and the Golden Meadows Exploration Project. The Decision Notice for the Golden Meadows Exploration Project at the Stibnite site specifically restricted commercial fuel haul to the Johnson Creek Road:</p> <p>Fuel haul associated with this project will not be allowed on the South Fork Salmon River road. Fuel haul, as described in the EA section 2.1.9 and Attachment A of this decision will occur only on Johnson Creek road.190 Emphasis not added.</p> <p>Johnson Creek Road (FS 413) is the only authorized route for transporting fuel in large trucks during snow-free conditions for implementation of this project.</p>		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	167	<p>Under no circumstances should hazardous materials or heavy truck loads be allowed on the South Fork Salmon River Road, even in the event that the Burntlog Route becomes impassable due to snow, weather conditions, or otherwise. The road bed for the South Fork Salmon River Road is not designed to withstand heavy truck traffic and the risk of spill risk is unacceptable. Instead, the Forest Service must consider keeping the Johnson Creek Road accessible year round. Similarly, the Forest Service should assess either how quickly the Johnson Creek road could be plowed or consider that both Burntlog Route and Johnson Creek could be maintained for year round mine site access. We are concerned that if Burntlog Route becomes impassable for days to weeks or longer, Perpetua would seek emergency permission to haul hazardous materials and fuel necessary for operating the mine along the SFSR Road if the Johnson Creek Road is not plowed. Indeed, the Biological Opinion for the SFSR road contains no provisions for a hazardous materials or fuel spill. Moreover, it is our interpretation that the controlling</p>	HAZ	Perpetua will continue to coordinate training opportunities with regional Fire Departments (Yellow Pine, Cascade, Donnelly & McCall); Council, Riggins and New Meadows would be included in future training opportunities. Perpetua anticipates positioning a mixed Hazardous Materials Response Trailer at the Valley County Emergency Operations Center in Cascade, Idaho.

			<p>document for fuel and hazardous material hauling along the South Fork Salmon River is the July 1990 South Fork Salmon River Road EIS (File Reference: EM.11.0006) which placed strict limits on fuel transportation down this road. While fuel haul is not totally banned, the restrictions are severe. The SDEIS erroneously assumes that access road choice for the proposed SGP is an either/or proposition. This assumption is misplaced because statements by Perpetua’s consultants recommend maintaining both roads due to the likelihood that Burntlog Route would become impassable during the winter months.</p> <p>Further, because road choice is not binary, there may be additional beneficial and adverse effects on forest resources. Beneficial effects may include reduced potential for destructive avalanches that could dam the EFSFSR, damage the Stibnite Road, and/or impact aquatic habitat if an avalanche control program is used to maintain wintertime access between Yellow Pine and the mine site. By contrast, adverse effects could be experienced due to the increased number of helicopter flights and explosives used for avalanche control along both the Burntlog Route and the Stibnite Road, impacting wildlife. These effects must be analyzed if the Forest Service is to take a hard look at mine site access.</p>		
David Chambers	17634-A	13	<p>4.7.2.2 2021 MMP – Mercury and Mercury Containing Materials</p> <p>There will a significant amount of mercury produced by the mercury emission controls, presumably as elemental mercury, but the details on the mercury emission controls are not provided in adequate detail in the SDEIS. It is noted:</p> <p>“... total mercury content in flasks and other waste streams to be disposed offsite is 10.9 tons per year with 10.7 tons consisting of metallic mercury in flasks.”</p> <p>This is a significant amount of mercury, which will require disposal. In the SDEIS it is not stated where mercury emission control residue will be disposed. The responsible way to dispose of this mercury would be ship it to a designated mercury disposal facility. The other option would be to dispose of the mercury in the TSF. Although this is probably a legal option, it also this mercury potentially more available than it would be if disposed of in a designated mercury disposal facility.</p> <p>In the following subsection (4.7.2.2 2021 MMP – Water Treatment Plant (WTP) Residuals), it is noted; “The WTP would produce a residuals slurry that would be disposed in the TSF.”</p> <p>It is clear from the statement that the TSF will be for the disposal of water treatment plant sludges, but it is not clear what will be done with the mercury emission control waste. The disposition of the mercury from the emission controls is an important issue, and needs further disclosure and discussion in the SDEIS.</p>	HAZ	The requested information has been added to the Mercury and Mercury Containing Materials subsection of Section 4.7.2.2 of the Final EIS.
Samuel Penney (Chairman)	19396	164	<p>4.2 Geologic Resources and Geotechnical Hazards</p> <p>The final antimony concentrate would be placed in 2-ton supersack containers ready for shipment off site for further refining. Add this to the risk of hazardous material spills in the project area and its waters and also enroute to the overseas refinery. The annual transport is estimated at to 730 truckloads. It is assumed that the concentrate, when sold, would be shipped to facilities outside of the U.S. for smelting and refining because there are currently no smelters in the United States with capacity for refining the antimony concentrate. This risk is unacceptable and grounds for denying the approval of this Project.</p>	HAZ	The Antimony Concentrate Handling subsection of Section 4.7.2.2 of the SDEIS discusses how the antimony sulfide concentrate would be handled at the site and in transport off site. In addition to placing the dry concentrate in closed supersacks, these containers would be placed into steel shipping containers at the mill. These would be sealed shut and locked before being placed on semi-trucks for transportation off site.
Samuel Penney (Chairman)	19396	221	<p>Fuels and Hazardous Chemicals subsection: The SDEIS recognizes the potential for small spills but does not discuss the large quantities of fuel and hazardous chemicals stored at the site and the potential environmental risks. It mentions environmental protection practices and design features would minimize the risk of accidental releases. Despite best plans and efforts, it seems large releases are possible given the remote location of the site, access challenges, and harsh weather conditions. This section should be expanded on.</p>	HAZ	Section 2.4.5.14 of the SDEIS and Table 2.4-11 discusses the quantities of hazardous substances to be used at the site, including the largest quantities. Section 4.7.2.2 states that the tanks that would contain hazardous substances would be located within engineered secondary containment sized to contain more than the quantity of the largest tank in the containment. Section 4.7.2.2 discusses the likelihood of spills of hazardous materials at the site and how they would be responded to in order to stop the spread of a spill and clean it up.
Samuel Penney (Chairman)	19396	291	Spill Risk	HAZ	The information requested in the comment is contained in Section 3.7.4.2 of the SDEIS.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			The SDEIS consistently downplays the potential risk of contaminants spilling into aquatic ecosystems. There should be a section in the FEIS that documents Perpetua's current record with fuel spills and Project related vehicles going off the road during trips to the Stibnite site. In Perpetua's recent past, there has been a fuel spill from an airplane crash carrying fuel, staff vehicles that have gone off the road and contractor vehicle rollovers. This all took place during the Golden Meadows exploration/ Administrative Settlement Agreement and Order on Consent stage with relatively low numbers of personnel traveling compared to this mine proposal.		
Samuel Penney (Chairman)	19396	293	The SDEIS fails to analyze the spill risk for the Middle Fork Salmon River watershed. The proposed Burntlog Route crosses over a ridge that separates the SFSR and the upper Middle Fork Salmon River watersheds. ⁴⁹⁰ In fact, the Burntlog Route reaches within 0.25 miles from an unnamed tributary of Big Chief Creek, which leads into Indian Creek and eventually the Middle Fork Salmon River. Spill risk to the Middle Fork Salmon River watershed needs to be analyzed. This Middle Fork subwatershed needs to be added to the analysis area along with impacts to fisheries and other aquatic organisms.	HAZ	SDEIS Section 4.7.2.2 describes spill risk, prevention, and response along the Burntlog Route including risks at surface water crossings. The Final EIS has been revised to mention the potential effects of the segment of the Burntlog Route located along the divide between the Headwaters of the East Fork SFSR and the Upper Indian Creek watershed that drains to the Middle Fork Salmon River.
Samuel Penney (Chairman)	19396	294	The percent of access routes that are located in riparian conservation areas is insufficiently quantified. The SDEIS notes that 6.5 miles or 18% of the 36-mile Yellow Pine Route is located within 100 feet of streams. It is unclear how the Yellow Pine Route was calculated as a 36-mile distance or why the riparian area is only considered within 100 feet of a stream channel. The Boise National Forest Land and Resource Management Plan is useful in calculating the percentage of routes in close proximity to streams. Using guidance from this document, 61% of Johnson Creek Road is located within the riparian conservation areas buffer. Considering the high proportion of roads in riparian conservation areas, the risk of a spill reaching surface water needs to be properly analyzed. The measures included in the Spill Prevention, Control and Countermeasure Plan would reduce the potential for a spill to reach downstream waters, yet there is no guarantee of no effects to aquatic life.	HAZ	The acreages of Project-related disturbance to riparian conservation areas are presented for each SGP component (including roads) in SDEIS Table 4.11-1.
Samuel Penney (Chairman)	19396	295	The SDEIS falsely claims to qualitatively assess risk of vehicular accidents. The SDEIS cites data with very low rates of large truck accidents resulting in spills of hazardous material. ⁴⁹³ However, these data are assumed to be from mostly straight, multi-lane, paved highways, in stark contrast to the steep, sinuous, narrow dirt roads associated with the Project. The SDEIS acknowledges that statistics for haul truck road accidents on county roads and/or in mountainous terrain are very limited, ⁴⁹⁴ but that does not make it appropriate to use data comparatively from paved roads to suggest that the risk of spills in the SFSR watershed is very low. Equally unacceptable is the SDEIS making the assumption that transportation on these roads would be safer than highway roads because there is less traffic and lower speeds.	HAZ	A revised incident risk analysis for hazardous materials has been added to Section 4.16.2 of the Final EIS. This includes an analysis of longer transportation routes on existing highways than was included in the SDEIS and examines recorded and predicted incident rates along those highways including incidents involving hazardous materials.
Samuel Penney (Chairman)	19396	296	The SDEIS lacks any analysis on the risk of fuel spills from airborne traffic. Indeed, an airplane crashed and spilled fuel at the site in February 2012, releasing 100 gallons of diesel fuel. The SDEIS does not describe how air traffic will arrive at the site during the life of the mine. Analysis of the risk of fuel spills from airborne traffic is imperative, and an air route that avoids flying over critical habitat for Endangered Species Act-listed fish species should be detailed.	HAZ	Measures to protect stream channels from spills associated with aircraft are described in Chapter 2 of the EIS. The impact analysis includes implementation of these measures.
Samuel Penney (Chairman)	19396	297	The SDEIS concludes that design features and permit stipulations and regulatory requirements from state and federal agencies would reduce the risk of spills and ensure that effective response is provided should a spill occur. ⁴⁹⁶ Anyone who has traveled along the EFSFR or Johnson Creek during spring stream flows understands that it would be nearly impossible to contain a spill during high flows. Once again the SDEIS relies heavily on professional judgment regarding the use of BMPs with little to no analysis of spill risks. The Tribe recommends quantifying all hazardous materials being taken to the site, total number of trips in riparian buffers and running different spill risk scenarios.	HAZ	A revised incident risk analysis for hazardous materials has been added to Section 4.16.2 of the Final EIS. This includes an analysis of longer transportation routes on existing highways than was included in the SDEIS and examines recorded and predicted incident rates along those highways including incidents involving hazardous materials. Discussion of certain potential spill scenarios has also been added to Section 4.7.2.
Samuel Penney (Chairman)	19396	318	The potential and impact of antimony concentrate entering a waterbody from a spill should be evaluated and documented.	HAZ	Descriptions of the potential effects of certain spill scenarios, including antimony concentrate, have been added to Section 4.7.2 of the Final EIS.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Samuel Penney (Chairman)	19396	320	The transportation of antimony from the site to the shipping yard should be detailed. Antimony concentrate bags will need to be transported from the site along roads with listed fish species such as the Snake and Columbia River. Will the concentrate be barged down these rivers?	HAZ	SDEIS Section 2.4.5.7 describes the containers and methods used to ship antimony concentrate from the site to a commercial loading facility. The specific methods and routes for antimony concentrate shipment from a loading facility would depend on the location of the receiving refinery and would be subject to transportation requirements for hazardous materials as regulated by the Department of Transportation.

Elizabeth Barnes	6652	3	p. 2-110 Limestone is the primary method for decreasing soluble heavy metal concentrations and moderating pH levels. However, no estimate is provided on the potential total volume of limestone that will be used throughout the mine's operation. Or, where the limestone will be sourced from and what is its purity standard. While limestone has benefits, there are unaddressed risks associated with its use such as: deposition of fine limestone particles in river beds and loss of substrate diversity, deposition of heavy metal particulates as the decreasing pH draws them out of solution, and inconsistent results of buffering at high flows. The project area has extremely high concentrations of arsenic, antimony, and aluminum that will be exacerbated by mining operations if allowed to proceed as planned. Additional mercury, lead, and copper exceedances are anticipated. The river systems that run through the impacted area and contact heavily contaminated water sources at multiple points (TSF runoff, underdrains, etc.), have very high flows in spring when the mountain snowpack melts. This is a critical time of year for fish migration and spawning and it is unlikely that any volume of lime will be able to neutralize the pH of high flow waters, being naturally acidic from snowmelt, and the result every spring for decades after mining ends that dissolved heavy metals will be carried for miles downstream impacting huge reaches of the Salmon River and generations of fish and all who eat them.	WTR	SDEIS Section 2.4.5.7 describes how 130,000 to 318,000 tons of limestone would be mined annually on site to meet the limestone and lime needs of the Project for pH adjustment. The pH adjustments would be associated with ore processing with the resulting tailings placed in the lined tailings storage facility. Dust controls associated with the crushing of limestone and the lime kiln are also described in SDEIS Section 2.4.5.7 and would be utilized to inhibit dust and its deposition in the watershed. The Project includes water treatment and water management controls to improve or maintain analyte concentrations in the Project area streams. These streams are circumneutral under existing conditions and do not exhibit acidic pH values.
Elizabeth Barnes	6652	6	Table 3.9-5 The Acid-generating potential (NAG) of the SGP ore rock is extremely high, with acidity as extreme as 2.6 pH (Alaskite), 3.4 pH (Quartz-Monozite-Alaskite), 3.6 pH (Granite). Quartz-Monozite-Alaskite has the highest risk and is the most abundant mined material in the SGP, comprising 26-40% of deposits in Yellow Pit, and 48-70% in Hangar Flats Pit. These ores will have the greatest impact to water chemistry at and downstream the project area, especially at the ore stockpiles and ore tailings pile. The tailings pile underdrain will flow directly into Meadow Creek, making acid-generation highly likely at this point and acid mine waste will not be preventable, or addressed until it is too late. This will become increasingly problematic post-closure as liners degrade exponentially over time. In addition to direct outflows and underdrains, ore tailings and open pit walls and backfill interact with the groundwater, and there will be no mechanism to prevent chronic or acute releases of acid mine waste contaminated with antimony, arsenic, aluminum, and mercury all above water quality standards. Lead (pb) leachability also exceeds standards (Table 3.9-6b), why is this not thoroughly discussed as a risk? The Quartzite-Monozite-Alaskite Ore also has a NPR >1.5, beyond the threshold for potentially-acid generating material, creating an extremely strong likelihood of acid mine waste release.	WTR	Acid-generating ores would be processed and treated with lime then placed in the lined tailings storage facility where they would not contribute acidic drainage to the environment. Other mined materials such as development rock and pit wall rock are not expected to generate acidity. Instead, future water chemistry conditions are expected to be related to neutral pH leaching of mined materials rather than acidic drainage.
Elizabeth Barnes	6652	7	Despite the major risk and suitable conditions for the development of acid rock pollution, the tailings piles will be contaminated with high levels of heavy metals and other pollutants that will dissolve into water even without acidic conditions. It is stated that "a few constituents are mobile under neutral to alkaline pH conditions, including aluminum, antimony, arsenic, manganese and mercury, which were frequently leached (in Humidity Cell Tests) in concentrations above the strictest surface water quality standard. In addition, sulfate, selenium, TDS, copper, cadmium, and zinc were occasionally elevated (p. 3-166)." Furthermore, the HCT test did not use first flush water flows and chemistries (p. 3-168), which can be fully anticipated to flush huge amounts of dissolved pollutants from the SGP far down the Snake River. These risks of acid waste rock generation and heavy metal contamination are clear as day in the tables and analyses, but are largely trivialized and unscientifically dismissed in the EIS text to create a misleading read of the true environmental impacts and destruction of the watersheds that can be clearly	WTR	The characterization of Project mined materials demonstrates that acidic drainage is unlikely to occur. Acid-generating ores would be subject to oxidation of sulfides followed by neutralization and placed in a lined tailing storage facility. Development rock and pit wall rock do not exhibit acid generating properties in laboratory test work and acid generation has not been observed in the historical Yellow Pine and West End open pits.

			anticipated to occur. To be particularly negatively affected are the spawning reaches for Chinook Salmon, Steelhead, and Bull Trout in and immediately downstream the project area. Why is acid mine drainage so dismissed albeit highly probable?		
Elizabeth Barnes	6652	8	Will cyanate be tested for in water outflows and water quality testing sites? What is the expected concentration? And impacts to aquatic life?	WTR	Cyanate is an intermediate stage in the breakdown of cyanide to carbon dioxide and nitrogen by alkaline oxidation. The Project uses membrane treatment to remove cyanide from solution instead of alkaline oxidation. Therefore, monitoring would focus on cyanide measurements instead of cyanate. Cyanate has low toxicity properties and tends to convert into carbon dioxide and nitrogen in surface water environments.
Elizabeth Barnes	6652	11	4.8.52 States that post-closure the streamflow system would "return to a stable seasonal pattern similar to existing conditions." Yet, permanent installation of geosynthetic liners in piles will increase overland flow and intensify peak flows. These peak flows disproportionately contribute to heavy metal source pollution from the historic mine area to downstream reaches. Overland flow and peak flow will also be intensified by impermeable surfaces of mine facilities, parking, roads, and loss of tree cover. What is the anticipated increase in overland flow due to installation of impermeable surfaces?	WTR	SDEIS Section 4.5.2.2 describes the reclamation cover materials that would be placed over geosynthetic liners. Upon revegetation of the cover materials, overland flow would resemble existing conditions.
Elizabeth Barnes	6652	12	Figure 4.9-1 What are "process losses?" Their quantity, composition, phase state, transport mechanism, and impacts?	WTR	Process losses would consist of evaporation from the process, connate storage of tailings water within the TSF, or residual moisture retained in the antimony concentrate. Evaporation releases water vapor to the atmosphere while previously dissolved constituents remain in the process. Water contained in the settled tailings would be retained by the liner system. Moisture retained in antimony concentrate would remain in liquid form until processed offsite when it would evaporate or become a residual of the concentrate process.
Elizabeth Barnes	6652	13	Figure 4.9-1 With the anticipated degradation of geosynthetic liners, what will prevent the tailings slurry from leaching indefinitely and at an increasing rate post-closure? p. 4-211.	WTR	Leakage rates through the tailings storage facility liner are described in SDEIS Table 4.9-7 and Section 4.9.2.2. Leakage rates through the liner depend on the water pressure from the tailings on the liner and would decrease over time during the closure and post-closure periods as the tailings dewater.
Elizabeth Barnes	6652	14	4.9-1 Why wont tailings storage facility outflow water be treated? It will contain water from open pits, ore stockpiles, tailings slurry, contact water ponds, process facilities, and truck shop, yet it is allowed to flow directly into Meadow Creek via IDPES outfall?	WTR	Tailings storage facility outflow would be recycled for process water use and ultimately treated during closure. Tailings storage facility underdrain flow would consist of groundwater emerging below the facility liner and would not be in contact with the tailings materials.
Elizabeth Barnes	6652	15	Table 4.9-9 What are the Predicted Maximum Concentrations in Water Treatment Plant influent for cyanide, cyanate, and TDS?	WTR	During operations, process water containing cyanide would be reclaimed and reused as process water. Water treatment of process water would be initiated in the post-closure period. Influent concentrations for cyanide and TDS during the post-closure period are presented in SDEIS Table 4.9-9. The selected water treatment process would not involve alkaline oxidation to form cyanate from cyanide.
Elizabeth Barnes	6652	16	4-202 What is the purpose for reroute Meadow Creek over the seepage pond at mine closure? This decision will delay remediation, as slurry pond needs to sufficiently dry before revegetation and increases surface water contact with highly contaminated materials.	WTR	The restoration of Meadow Creek over the tailings storage facility creates wetland areas to offset the removal of existing wetland areas by the tailings storage facility construction.
Elizabeth Barnes	6652	17	4-219 The basis for predicting operational and post-closure effluent water quality, and therefore stream quality, are based on "the MINIMUM of the predicted water treatment plant influent or the TARGET effluent concentrations was used." This basis for analysis will result in understated risks and the best case scenario, rather than the most likely case scenario.	WTR	SDEIS Table 4.9-10 presents the treatment plant effluent objectives. If influent water has a lower concentration than these objectives for an analyte, then the effluent water would have a lower concentration than these objectives as well, no greater than the influent concentration. Therefore, the resulting analyte concentrations in water treatment plant effluent are not understated and represent the reasonably foreseeable scenario.
Elizabeth Barnes	6652	18	4-219 Why will a temporary water treatment plant be permitted? Operations should not start until a permanent water treatment plant is up and running. What is the capacity of the temporary treatment plant? Are effluent standards, and predicted maximums, the same for the temporary and permanent treatment systems? How many years will construction of the permanent water treatment facility take?	WTR	A temporary water treatment plant would be needed to control effects on water chemistry during construction and commissioning of the permanent water treatment plant. The temporary treatment plant would be utilized during the project construction phase which would be up to three years.
Elizabeth Barnes	6652	20	4-212 What is the standard error for the expected maximum water volume to enter the Water Treatment Plant? Is 100 year flood an applicable maximum given the anticipated increase in flood events due to	WTR	The range of influent volumes to the water treatment plant based on a 120-year precipitation record are described in SDEIS Figure 4.9-9. During operations, these volumes include

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			climate change effects on precipitation trends? What are the anticipated volumes of water to be produced in the TSF and contact ponds, in relation to the Water Treatment Facility capacity? What is the remediation plan for contact water ponds?		dewatering water and contact water in excess of the make-up water demand for processing. Water from the tailings storage facility would be reclaimed and recirculated for process use. In the post-closure period, these volumes include contact water and tailings storage facility drainage. These volumes are described in the lower graph shown in SDEIS Figure 4.9-9. During operations and closure, contact water would be collected and used for process make-up water or treated for discharge. Following closure and into the post-closure period, placement of membrane liners, reclamation cover material and revegetation would eliminate contact water by inhibiting contact of surface water with mined materials.
Elizabeth Barnes	6652	21	Why is there no remediation plan for Hangar Pit or other mine pits that will have indefinite contact with groundwater and be an eternal source of heavy metal pollution to the local watershed?	WTR	SDEIS Section 4.9.2.2 describes the effects of groundwater interaction with pit backfill materials on groundwater chemistry and the estimated pore water chemistries. Groundwater chemistry would be subject to point of compliance regulations under the Idaho Ground Water Quality Rule with mitigation requirements determined through application of that rule. The point of compliance for the project has not yet been determined.
Elizabeth Barnes	6652	22	4-219 The use of both Meadow Creek and the East Fork Salmon River spread the potential for contamination to two critical creeks, what is the justification for this? Flows could be increased with other water sources.	WTR	Discharges to Meadow Creek and the East Fork SFSR would consist of treated water meeting discharge requirements established through the IPDES permit.
Elizabeth Barnes	6652	24	4-220 Will the water treatment facility be a permanent installation on the landscape, or will it be decommissioned and remediated to a natural state? At what timeline?	WTR	The water treatment facility would remain in place until water treatment operations would be no longer needed to treat effluent from the tailings storage facility or contact water. The time period for treating effluent is expected to be approximately 40 years. When the water treatment facility is no longer required, it would be removed and reclaimed.
Elizabeth Barnes	6652	25	4-220 What is the explanation for the discrepancy between the predicted 25,000-50,000 g wastewater flow, but only 2,000 g per year effluent? How will 25,000 gallon/day flow affect flow rates in streams?	WTR	The 2,000 gallons per minute is the design capacity of the mine water treatment plant for treating dewatering water and contact water. The 50,000 and 25,000 gallon per day volumes are the design capacities for the sanitary wastewater treatment plan for workers housed on site.
Elizabeth Barnes	6652	26	4-220 There is no quantification of sewage wastewater chemistry, or temperature? This debases any final analysis of mine impacts of fish populations as this is critical information. Many commonly used personal care products are not addressed in water treatment systems and can have deleterious effects on aquatic lifeforms, not addressed in the EIS. Why not?	WTR	Sanitary wastewater treatment would meet discharge standards imposed by the IPDES permit. Effects of water treatment on stream temperature were described in SDEIS Section 4.9.2.2.
Elizabeth Barnes	6652	28	4-225 The West End Lake Pit is predicted to be a long-term source of Antimony, arsenic, mercury during operation and post--closure. This pit interacts with ground water and will be a source of heavy metal pollution downstream for the indeterminable future. Antimony is toxic to embryonic and larval stages of fish at very low levels (Nam et al. 2009). Arsenic exposure in the aquatic environment causes bioaccumulation in aquatic organisms and can lead to physiological and biochemical disorders, such as poisoning, liver lesions, decreased fertility, cell and tissue damage, and cell death (Bears et al. 2006; Ribeiro et al. 2005). "Mercury is one of the most serious contaminants threatening our Nation's waters because it is a potent neurological poison in fish, wildlife, and humans.. (USGS 2018)."Arsenic and lead will also exceed water quality standards in the Hangar Pit backfill (Table 4.9-15). The claims made in the cumulative effects section that fish habitat will suffer no net loss, and rather, will be expanded under the operation of SGP alternatives, is completely debased and unscientific given the multiple documented sources of heavy metal pollution that is certain to be sourced from tailings underdrains, contact water ponds, ore stockpiles, and backfilled pits. The EIS is highly deceiving in its description of cumulative effects to fish. Furthermore, there is no analysis whatsoever of the effects of anticipated heavy metal leaching on the aquatic invertebrate food chain, without which the fish populations cannot survive. I cannot state with enough emphasis the certainty, given the predicted water chemistries, that the project area will be inhabitable to fish populations, or for many miles downstream as heavy metals will be released and will persist in the environment, decimating invertebrate populations, accumulating in fish and other wildlife populations, and ultimately denuding the project area and downstream reaches of life and productivity. Why are water quality exceedances not thoroughly discussed in the cumulative effects on fish sections?	WTR	The water chemistry associated with the West End Pit lake and its effects on groundwater are described in the analysis presented in SDEIS Section 4.9.2.2. The effects pit lake and pit backfill water chemistry were incorporated into the surface water chemistry evaluation. Antimony, arsenic, and mercury present in contact water would be subject to water treatment. Tailings underdrain water has the chemistry of existing groundwater because the underdrain collects groundwater coming to the surface below the liner which would not be in contact with tailings materials. The resulting effects of groundwater chemistry and water treatment on surface water chemistry were incorporated into the effects analysis for fish as described in SDEIS Section 4.12.2.2.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Elizabeth Barnes	6652	30	4-230 What is the potable water source for the mine workforce, during operation and for the decades postclosure that water treatment will be required?	WTR	There is an existing potable water well and potable water treatment system operating at the site. As described in the Water for Potable Use subsection of Section 2.4.5.10, there would be water supply wells installed for the worker housing facility. Operation of the potable water supply systems would comply with State requirements for monitoring and treatment.
Elizabeth Barnes	6652	31	4-243 The only reason that no exceedances are predicted is because the method for imputation was using the effluent targets, and not the anticipated maximums. Why? Under maximum metal concentration conditions, there absolutely will be exceedances and this is an extremely deceitful presentation of information considering the maximums are provided in tables and could very well be used in the calculations of effluent chemistry when compared to treatment effectiveness and capacity.	WTR	Achievement of effluent water treatment targets would be required by permit and therefore represent the reasonably foreseeable water concentrations.
Elizabeth Barnes	6652	32	4.9-21 Upstream reaches of multiple streams flow through the TSF, adding a continuous source of water contact, and primarily acidic rainfall and snowmelt. Why not relocate the tailings pit to occupy one drainage, instead of 3? Given the predicted exceedances of antimony from multiple documented sources (TSF, contact ponds, ore stockpiles, open pits), why is antimony predicted to decrease post-closure, but arsenic predicted to increase?	WTR	The tailings storage facility design fills the native topography to approximately the crest elevation of the completed tailings embankment. At this elevation, the tailings would occupy the Meadow Creek drainage and the lower portion of two tributary drainages. Exclusion of the two tributary drainages would require two embankment dams and channel diversions that would not result in reduced environmental effects. During operations meteoric water entering the TSF would become part of the process water recirculation and not be discharged to the environment. As part of the reclamation plan, the TSF would be covered with an impermeable membrane that itself would be covered with clean reclamation materials which would prevent contact of meteoric water with the underlying tailings. Monitoring data for Meadow Creek indicated that stream water is circumneutral and not acidic (e.g., SDEIS Table 3.9-9). Antimony concentrations are more affected by the removal of legacy materials from the drainage that contribute antimony to surface water when leached. Mined materials associated with the Project do not produce antimony to the same extent when leached. For arsenic concentrations, removal of the legacy materials that contribute arsenic to surface water when leached, results in a reduction in stream arsenic concentrations during operations. However, mined materials associated with the Project produce similar arsenic concentrations in the post-closure period when leached.
Elizabeth Barnes	6652	33	4-252 Given the increases in antimony, arsenic, mercury, and lead, why are "effects on surface water concentration expected to be negligible?" This seems like an unfounded claim given the data provided in multiple tables.	WTR	Effects on surface water chemistry are based on comparison to existing conditions and the predicted surface water chemistry effects of the Project resulting in lower or similar analyte concentrations compared to existing conditions.
Elizabeth Barnes	6652	34	4-225 The concentrations of antimony and arsenic and mercury in groundwater from contact with the West End Pit will be permanently above water quality standards. Why are the effects of these heavy metal exceedances on fish, humans, invertebrates, and waterfowl not discussed or incorporated into the cumulative effects section?	WTR	Effects of the West End Pit lake on groundwater chemistry are direct effects from the Project and are therefore described in Chapter 4 in SDEIS Sections 4.9.2.2 (water resources), 4.12.2.2 (fish and aquatic resources), 4.13.2.2 (wildlife), and 4.18.2.2 (public health and safety). Human and ecological exposure to groundwater is limited, making groundwater effects on surface water chemistry the primary exposure assessed.
Elizabeth Barnes	6652	36	4-283 Will revegetation be delayed permanently if water temperature fails to meet standards?	WTR	Revegetation would occur promptly following placement of reclamation cover material on facilities. Attainment of target revegetation would be monitored and adjusted as needed until water temperature standards are met. A mitigation measure for water temperature has been added to the Final EIS.
Elizabeth Barnes	6652	37	4-285 It is stated that there will be no surface water impacts because it is a renewable resource? What does this mean, given the indefinite contact of surface water with multiple sources of contamination within the project area	WTR	The text has been clarified to indicate that water management and reclamation activities protective of surface water quality would improve or maintain the existing conditions for surface water as a renewable resource.
Elizabeth Barnes	6652	39	4-348 What is the rationale for stating that a spill would have effects that are "moderate, temporary, and localized?" Wouldn't a major spill have effects that are severe, permanent, and widespread. The risk of a spill is extremely downplayed in the EIS and very little information or analysis is provided on the potential environmental impacts. The EIS is written with extremely rose-colored glasses and I pray that officials use the data in the tables and their own minds to see the clear and present danger posed by mine operations in this location with extremely high naturally occurring heavy metal concentrations, multiple	WTR	The SDEIS accounts for the spill prevention and spill response measures incorporated into the Project that would minimize the consequences of spills. The TSF is designed to be a zero discharge facility while operating to contain process water. All facilities that would store or use liquid hazardous materials would be constructed with spill containment to prevent releases to the environment if a spill from primary containment occurred. Spills outside of containment would quickly be responded to by mine employees and the spilled materials

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			headwater streams running through contaminated mine material, and a poorly-conceived water treatment plan that allows multiple sources of contaminated water to go untreated and rather run through effluent out-pipes. Even if concentrations at the point of release are below standards (which would be extremely unlikely given the data) the accumulation of these metals downstream and in the Salmon River watershed food chain are highly likely and will not be measurable until mediation is far too late. The cumulative effects statement only speaks on the physical habitat distances expected to be physically accessible, and does not consider the poor water quality that will occur in these reaches. I pose to officials, would you eat a fish reared below the TSF? Because numerous wildlife will.		would be contained and cleaned up which would not allow permanent and widespread impacts. Contact water would be collected and either used within the process or be treated in accordance with permitted outfalls before discharge to surface streams.
Jack Nelson (Representative, District 26)	7149	3	The net benefit of the project will include 47% reduction in arsenic in the East Fork South Fork of the Salmon River on site and a reduction of 40% in arsenic off-site. All of these benefits will happen because of private investment and a commitment to the environment through modern mining practices.	WTR	No further response required. General in nature or position statement.
Britt Raybould (Representative)	7180	3	Moreover, Perpetua has shown its committed to responsible mining practices. As outlined in the Supplemental Draft Environmental Impact Statement (SDEIS), Stibnite Gold will reduce 47% of arsenic in the East Fork South Fork Salmon River on site, as well as a 40% reduction of arsenic in the East Fork South Fork Salmon River off site. Additionally, antimony is critical for long duration storage batteries, which will help assist in the move toward cleaner energy.	WTR	No further response required. General in nature or position statement.
Brooke Green (Representative, District 18)	7183	4	The company will also pick up, reprocess and safely store over 10.5 million tons of legacy mine waste and store it inside of a double lined and capped facility to prevent it from interacting with both ground and surface water like it does today.	WTR	No further response required. General in nature or position statement.
Jason Monks (Representative)	7208	4	And despite not making any money from the mineral resource yet, they've already started addressing water quality at Stibnite. This past summer, they began voluntary work to reroute waterways away from historic mine waste and next summer they will start picking up and storing over 300,000 tons of historic mine waste that poses a threat to the rivers that go through their project site. This kind of work shows that they are genuine in their commitment to make Stibnite better than it was when they found it.	WTR	No further response required. General in nature or position statement.
Susan Dorris (Mayor, Donnelly)	8432	5	The MMP identifies significant water enhancements. An important point is that the MMP has specific actions that will improve the overall ecological standing and that has a trickle-down effect that will improve water quality. Also, the fish tunnel although not a water quality issue is an enhancement that will be beneficial for the EFSFSR Salmon spawning areas and the restoration of the river back over the Yellow Pine pit will also increase diversity of fish in the upper reaches.	WTR	No further response required. General in nature or position statement.
Treg Bernt (Senator, District 21)	10237	2	This site has been mined over 100 years and was effectively abandoned by past operators and responsible parties. There is over 10 million tons of legacy waste and tailings that are degrading water quality. At certain places, arsenic can reach 700 times the drinking water standard. Perpetua wants to fix these legacy issues. In fact, some of the benefits of the project include a 47% reduction in arsenic in the East Fork South Fork of the Salmon River on site and a 40% reduction in arsenic off-site. This important work can only be done with private dollars that Perpetua will be bringing to the table.	WTR	No further response required. General in nature or position statement.
Snake River Fund	16536	4	The SGP presents numerous recreational, environmental, and sociocultural concerns. Perhaps the most immediately problematic of those concerns is the health of waterways adjacent to, and downstream from the operations site and of waterways that parallel proposed access roads. As a result of the SGP, stream temperatures are predicted to be elevated above baseline conditions for up to 100 years (SDEIS ES-15). The Forest Service's own Climate Shield identifies these potentially impacted streams as being an indispensable cold water refuge for native trout. Furthermore, potential contamination from tailings and hazardous waste spillage along access roads carries the potential to irreversibly deteriorate designated critical habitat for ESA-listed Chinook salmon, Forest Service listed sensitive westslope cutthroat trout, steelhead trout, and bull trout.	WTR	The SDEIS discusses the Project effects on stream water temperature (Section 4.9.2.2) and the stream water temperature effects on fish (Section 4.12.2.2). Section 4.7 describes the potential for spills of materials and the measures that have been included in the designs and operational practices to reduce the potential for impacts of spills. The Project Reclamation Closure Plan includes measures to address the stream temperature effects and the mitigation measure provided in SDEIS Section 4.9.3 address potential uncertainty in the successful implementation of the Reclamation Closure Plan.
Hendrickson, Emily (President, Women's Mining Coalition)	17429	4	Although your October 21, 2022 Dear Reader Letter announcing the availability of the SDEIS accurately characterizes Perpetua's Modified Mine Plan (MMP) as "reducing surface disturbance and anticipated environmental impacts," the SDEIS does not clearly or consistently describe these environmental improvements. The data presented in the SDEIS (especially in the figures and tables) clearly show the project will substantially improve water quality in the project area and downstream from the project and	WTR	The effects of the removal of fish barriers and restored habitat including the Stibnite Lake are described in the Fish Resources and Fish Habitat section of the SDEIS Executive Summary. A description of the benefits of the Blowout Creek remediation has been added to the Surface Water and Groundwater Quality section of the Executive Summary.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>restore miles of stream and fish habitat. The Forest Service needs to improve the consistency and clarity of the text of the Final EIS, which can be readily accomplished by editing the document to ensure consistency and to make more use of the figures and tables that illustrate and quantify the water quality improvements and the stream segments that will be restored. The Executive Summary needs to present a more balanced discussion of impacts. As written, it does not clearly describe the environmental benefits associated with the proposed restoration activities in the MMP. Instead, the Executive Summary emphasizes adverse impacts rather than giving equal weight to the water quality improvements and habitat restoration that would result from the MMP. The Environmental Consequences chapter of the SDEIS contains abundant and detailed analyses and data that clearly show water quality and fish habitat/stream restoration improvements. However, these beneficial impacts are not clearly or consistently discussed in the Executive Summary. The Executive Summary also omits two significant environmental restoration measures integral to the MMP:</p> <ol style="list-style-type: none"> 1. Constructing Stibnite Lake in the backfilled Yellow Pine Pit to mitigate the loss of the Yellow Pine pit lake fish habitat area and to minimize fluctuations in stream temperatures; and 2. The reclamation activities that will eliminate the significant sedimentation problem at Blowout Creek. It is inappropriate to exclude these beneficial impacts from the Executive Summary. The Executive Summary should explain that Perpetua added Stibnite Lake to the MMP to respond to public comments received on the DEIS about temperature fluctuations in this segment of the East Fork of the South Fork of the Salmon River (East Fork) and the need to replicate the lake habitat that currently exists in the Yellow Pine Pit. WMC notes that words that would typically be used to describe beneficial impacts are used sparingly or are completely absent from the Executive Summary. For example, the word “positive” is used only once in the Executive Summary to describe public health and safety benefits (see Page ES-26.) The word “positive” is not used to describe the documented water quality improvements or the restoration of stream and fish habitat. The word “improve” is used on Page ES-15/16 to describe water quality impacts. However, it is used in a confusing way stating: The MMP would improve some of the existing water quality conditions observed in Meadow Creek and the East Fork SFSR by removing and repurposing legacy mine wastes. However, the 2021 MMP would have direct permanent impacts on water quality, as it would contribute new sources of mine waste material to the East Fork SFSR drainage. This is the only acknowledgement in the Executive Summary that the MMP will improve water quality. But the second sentence shown above casts doubt on the improvements by suggesting that the new mine wastes would create direct and permanent water quality impacts without discussing the numerous project design features to prevent, limit, or mitigate impacts from the project development rock and tailings. 		
Hendrickson, Emily (President, Women's Mining Coalition)	17429	5	<p>The Surface Water and Groundwater Quality section in the Executive Summary fails to clearly explain that the Site-Wide Water Chemistry (SWWC) predictive modeling results for the downgradient prediction node at YP-SR-2 clearly show water quality improvements during and after mining. The data presented in Figures 4.9-21 and 4.9-25 make it easy for the public to understand the beneficial water quality impacts because these figures clearly document that the MMP will improve water quality at YP-SR-2. The Executive Summary in the Final EIS needs to clearly state that the SGP will achieve significant reductions in arsenic levels (40 percent) and antimony levels (58 percent) as predicted at YP-SR-2, compared to baseline conditions. The Executive Summary should either reference Figures 4.9-21 and 4.9-25 or include these figures.</p>	WTR	<p>The text in the Surface Water and Groundwater Quality section of the Executive Summary has been revised to clarify that predicted stream water metal concentrations are improved or consistent with the existing conditions.</p>
Hendrickson, Emily (President, Women's Mining Coalition)	17429	8	<p>The Final EIS needs to use the data in the SDEIS and the Specialist Reports in order to be more transparent about the impacts and benefits associated with the SGP. Both the Executive Summary and the Final EIS should present a more balanced discussion of both the positive and the negative impacts. As currently written, the Executive Summary presents a partial and incomplete snapshot of the project that inappropriately minimizes the project benefits. WMC has the impression from reading the Executive Summary that the Forest Service has purposefully downplayed and underemphasized the environmental benefits (especially the water quality improvements) that will result from the remediation activities integral to the MMP. The Final EIS should highlight these benefits and discuss them in the context of improving the environmental and ecological conditions in the Payette and Boise National Forests.</p>	WTR	<p>The text in the Surface Water and Groundwater Quality section of the Executive Summary has been revised to clarify that predicted stream water metal concentrations are improved or consistent with the existing conditions.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Hendrickson, Emily (President, Women's Mining Coalition)	17429	10	A careful reading of Section 4.9 of the SDEIS reveals that the MMP will result in significant environmental improvements to sitewide water quality. However, it is not easy to arrive at this understanding because certain paragraphs in this section obscure this result by making statements that are inconsistent with the data in the document. Out-of-context localized or partial assessments that omit a bigger-picture evaluation and misstatements of facts that are correctly presented elsewhere in the document are other sources of confusion in this section. The SDEIS and the Forest Service's August 2022 Water Quality Specialist Report include lengthy discussions of the results of the new SWWC predictive model. As explained in the Specialist Report, the SWWC model integrates the following water sources in the project area: surface water, effluent from the water treatment plant, groundwater (including the projected groundwater quality beneath and downgradient from the tailings and waste rock disposal facilities), the backfilled Yellow Pine and Hanger Flats pits, and the West End pit lake. Figure 4.9-21 in the SDEIS, "Locations for Surface Water Chemistry Predictions Stibnite Gold Project, Stibnite, ID," clearly shows the SWWC predictive model results predict the MMP will significantly reduce the concentration of arsenic and antimony in streams in the project area compared to the existing baseline levels of these metals. This figure also shows that mercury levels remain the same after mining and are well below the regulatory standard. Despite the fact that Figure 4.9-21 presents a very useful and easy-to-understand synthesis of the SWWC predictive modeling results, the SDEIS glosses over this important finding and fails to properly acknowledge this significant environmental benefit in a way that makes it easy for the public to understand that water quality improvements will be one of the main environmental accomplishments that would result from the MMP. This finding should be highlighted in the Final EIS as one of the most important indicia of environmental improvement that will result from the SGP.	WTR	SDEIS Section 4.9.2.2 describes the Project effects on surface water chemistry and concludes that the Project improves or sustains existing conditions. The text in the Surface Water and Groundwater Quality section of the Executive Summary has been revised to clarify that predicted stream water metal concentrations are improved or consistent with the existing conditions.
Hendrickson, Emily (President, Women's Mining Coalition)	17429	11	The SDEIS creates confusion when it repeatedly states that the post-operational water quality will exceed water quality standards, because this statement creates the impression that meeting water quality standards should be the metric used to assess the project impacts and benefits. Comparing the post-operational water quality to surface water quality regulatory standards in a watershed that is designated as impaired under Section 303(d) of the Clean Water Act is meaningless and ignores the water quality improvements that the project will create. Although it is appropriate for the SDEIS to disclose that the predictive model shows that post-operational water quality will not meet regulatory standards, it is inappropriate to imply this finding represents a project shortcoming, with the implication that the MMP will not do enough to improve water quality. As clearly shown in Figure 4.9-21, the post-operational water quality will not exceed the mercury water quality standards. Figure 4.9-21 documents that the MMP will not change the post operational mercury levels in area streams, all of which are below the 12 nanogram per liter (ng/l) regulatory standard. Thus, the several statements in the text that the project will exceed water quality standards are not correct for mercury.	WTR	SDEIS Section 4.9.2.2 correctly identifies that surface water concentrations would be greater than regulatory standards. In its impact assessment of surface water chemistry, the SDEIS concludes that these concentrations represent an improvement or sustainment of existing conditions.
Hendrickson, Emily (President, Women's Mining Coalition)	17429	12	The Final EIS should clarify that the water quality modeling results that are presented in Figure 4.9-21 show that post-operational water quality will be significantly better than baseline conditions due to substantial reductions in arsenic and antimony levels. The Final EIS should eliminate the inconsistencies in the water quality discussion in the SDEIS. For example, the discussion on Page 4-251 of the SDEIS creates confusion by misrepresenting the modeling results at YP-SR-2: "Downstream of the project on the East Fork SFSR at node YP-SR-2 (below the confluence with Sugar Creek), predicted surface water chemistry is largely unchanged from existing conditions with some variability in predicted antimony, arsenic, and mercury concentrations during the operating and initial closure period (Table 4.9-21 and Figure 4.9-25)." (italics added for emphasis, bold in the original.) This discussion contradicts and is inconsistent with the data shown in Figure 4.9-21. (It also conflicts with the data shown in Figure 4.9-25 for the downstream monitoring point, YP-SR-2.) Both Figures 4.9-21 and 4.9-25 clearly show that there will be significant improvements in water quality at YP-SR-2 where the post-operational water quality is predicted to reduce antimony concentrations by 40 percent and antimony concentrations by 58 percent, compared to baseline conditions. It is completely incorrect to ignore these meaningful water quality	WTR	SDEIS Tables 4.9-18 through 4.9-21 quantitatively describe the predicted changes in water chemistry for all regulated constituents. Most of these constituents are largely unchanged by the Project. The notable reductions in arsenic and antimony concentrations are described in the text, tables, and figures in the surface water chemistry subsection of SDEIS Section 4.9.2.2.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			improvements and misleading at best to state that water quality is “largely unchanged from existing conditions.”		
Hendrickson, Emily (President, Women's Mining Coalition)	17429	13	Other sections of the SDEIS do a much better job of discussing the water quality improvements resulting from the MMP. For example, contrast the above-cited discussion on Page 4-251 with the discussion shown below on Page 4-522: “Under the SGP operations and closure, water quality of surface flow departing from the Operations Area Boundary would be the same or better than existing baseline conditions; therefore, there would not be impacts to the quality of downstream waterways...” These dramatically different statements create confusion, which needs to be eliminated in the Final EIS by conducting a through editing of the document for consistency to ensure that it clearly and consistently discusses the data and modeling results that are presented in the SDEIS and the Water Quality Specialists Report. A more consistent discussion of the SWWC-predicted water quality benefits accruing to the project in the Final EIS will improve the public’s understanding of the water quality benefits that would result from the MMP.	WTR	The effects of the Project on all regulated analytes are assessed as part of the NEPA analysis and described in Section 4.9.2.2. The conclusory statement represents the summary regarding surface water impacts utilizing the specific details and comparisons to regulatory standards described earlier in the section.
Hendrickson, Emily (President, Women's Mining Coalition)	17429	14	Another source of confusion are the lengthy and detailed discussions of groundwater quality in the SDEIS, which are misleading because they read as if they are final conclusions rather than the results of the groundwater quality component of the SWWC model. As clearly stated in both the SDEIS and the Water Quality Specialist Report, the ATSDR Public Health Assessment conducted for the existing mine site eliminated the groundwater as a drinking water pathway from consideration as a public health concern. Discussing the results of the groundwater quality modeling as if these results show there will be an adverse impact blurs the distinction between environmental impacts and model inputs. The Final EIS should clarify that the groundwater modeling results are a model input and do not represent an impact to a human receptor because the area groundwater is not a source of drinking water. The Final EIS should also explain that because the area surface waters are the ecological receptors for groundwater, the SWWC model appropriately incorporates the groundwater quality modeling results.	WTR	SDEIS Section 4.18.2.2 states that groundwater effects of the Project have a negligible effect on human health.
Hendrickson, Emily (President, Women's Mining Coalition)	17429	15	The SDEIS devotes numerous pages to discussing the predictive modeling results of operational and post-operational water quality at the model prediction nodes shown in Figure 4.9-21. Figures 4.9-22 through 4.9-25 present useful graphs showing the predictive modeling results at four of these nodes. Figure 4.9-21 clearly illustrates the benefits at the downstream node (YP-SR-2) in map view; Figure 4.9-25 is a graphical representation of the same benefits. The lengthy narrative could be shortened and improved by making greater use of Figures 4.9-21 through 4.9-25. Figures 4.9-22 through 4.9-25 are easy to understand and present data that clearly documents the water quality benefits associated with the MMP. Both the Executive Summary and Section 4.9 would be greatly improved by adding a narrative summary that succinctly synthesizes the modeling results shown in these figures. The Final EIS should include a summary that helps the reader understand these results and that emphasizes that the downstream prediction node (YP-SR-2) is the best place at which to measure the overall water quality benefits from the MMP. By making better use of Figures 4.9-21 and 4.9-25 and editing for internal consistency, Section 4.9 of the Final EIS can more clearly discuss the post-operational water quality benefits that would result from the MMP. The Final EIS should highlight these benefits with the objective of making it easier for the public to understand that the MMP will improve water quality. The discussion on Page 4-552 of the SDEIS, which states that water quality would be “the same or better than existing baseline conditions,” is an example of a factually correct and clear statement that should be replicated in the Final EIS.	WTR	The effects of the Project on all regulated analytes are assessed as part of the NEPA analysis and described in Section 4.9.2.2. The conclusory statement represents the summary regarding surface water impacts utilizing the specific details and comparisons to regulatory standards described earlier in the section.
von Lindern, Ian (Founder, Terragraphics International Foundation)	17436	23	Under the SDEIS, the TSF Embankment and Buttress will contain from 115,317 – 425,957 tons of arsenic, 117-378 tons of mercury, and 13,145 -17,566 tons of antimony. Compared to the DEIS Alternative, arsenic disposed in the TSF Dike /Buttress is increased by 210%, and decreased by 10% in the YPP and 66 % in the WEP. The HFP is backfilled with 14,618 - 53,995 tons of arsenic as opposed to water in the DEIS. Typical arsenic concentrations in DR backfill will range from 812 ppm to 3000 ppm, (average - 95th %tile), as compared to 656 ppm to 2422 ppm in the DEIS. Table SD11 summarized DR COC for the DEIS and Table SD3 summarized DR and Waste COC for the SEIS.	WTR	The composition and leachability of the TSF embankment and buttress and pit backfill material are incorporated into the water chemistry analysis as depicted in the conceptual diagrams shown in SDEIS Figures 4.9-2 and 4.9-15, respectively. The incorporation of arsenic concentrations in dust into the air quality assessment is described in SDEIS Section 4.3.2.2.

			<p>DR disposal SDEIS and DEIS are markedly different, and direct comparisons are difficult. Three of the DR surface repositories indicated in the DEIS have been eliminated and one subsurface pit has been added. Four (4) of the 10 DR haul road scenarios evaluated for both the DEIS and SDEIS air quality analyses are no longer applicable, and none estimate haulage to the TSF Dike/Buttress, the most utilized route under the new SDEIS Preferred Alternative. As a result, the relevancy of the air quality analyses supporting HR emissions calculations is suspect. However, these effects cannot be evaluated as the electronic links to the modeling files can no longer be accessed.</p> <p>All SDEIS Alternative DR repositories will be under a geo-synthetic cover and largely protected from meteoric waters for the life of the cover. In total, approximately 54% of SDEIS DR arsenic will be disposed in surface repositories and 46% in Pits, as opposed to 68% surface and 32% sub-surface disposal in the DEIS. Pit-disposed COCs will be exposed to groundwater wet/dry and redox cycles, and will release COCs to groundwater. Although additional protections will be afforded from meteoric waters, YPP and HFP subsurface disposal of COCs likely increases groundwater contact, leaching and discharge.</p> <p>The Forest Service should independently re-evaluate the air quality modeling and the relevance of the Haul Road characterizations, emission estimates, and carcinogenic risk assessments. Similarly, the release to groundwater and consequent downstream effects from YPP and new HFP should be re-evaluated.</p>		
von Lindern, Ian (Founder, Terragraphics International Foundation)	17436	24	<p>The largest component of total on-site arsenic (64%) is in ore. Under the new SDEIS Alternative, a projected 112M tons of pit ore will be produced containing 396,246 to 1,028,406 tons of arsenic (average - 95th%-tile). About 55%, 12%, and 31% of arsenic in Pit ore will be produced from the YPP, HFP and WEP, respectively. This a marked change from the DEIS Alternative reflecting 44%, 46% and 9%, respectively. These are significant differences, as the concentrations and chemical form vary among ores and can have important effects on the distribution, chemical form, toxicity, and disposition of arsenic in downstream metallurgical processes, disposal and releases, and behavior in environmental media. About 3% of ore arsenic is in historic wastes.</p> <p>Ores will be crushed and ground and subjected to flotation concentration. About 85% of arsenic in ore will go to concentrates and 15% to tailings. An estimated 9% of YPP arsenic, 30% of HFP arsenic, and 17% of WEP arsenic, or a total of 61,547 to 157,878 tons of arsenic will discharge with flotation tailings to the TSF. The chemical form of this arsenic is unclear, but likely varies by Pit source. An estimated 85% of arsenic in ore (348,766 – 894,462 tons) will be captured in gold flotation concentrates (54% of Site-wide As). The arsenic in these concentrates is pressure oxidized in a high temperature autoclave (POX) to liberate gold and will eventually go through cyanide (CN) leaching and detoxification (Detox) and be discharged to TSF. About 60% of total Site-wide As will be subjected to the POX/CN/Detox processes and undergo substantial chemical transformation.</p> <p>Neither the DEIS nor SDEIS addresses the arsenic content, geochemistry or chemical constituency in relation to these proposed metallurgic processes or waste characteristics. This omission is of considerable concern, as arsenic chemistry and toxicity are complex and species (valence) dependent. Solubility, bioavailability and toxicity are highly variable among mineral processing applications depending on other metal concentrations, pH, and oxidation-reduction status, among other factors. Only two, two-sentence statements in the entire SDEIS document address these issues: i) on page 2-51 Oxidation and Neutralization and ii) in Table 2.4-13 Proponent Proposed Design Features. Both allude to: “Perpetua would monitor levels of soluble arsenic in the tailings. If soluble arsenic levels are higher than anticipated, Perpetua would treat the oxidized concentrate with HAC prior to neutralization.”</p>	WTR	The arsenic contained within tailings would be managed within containment facilities that would inhibit environmental exposure during operations and long term with impermeable liners and clean cover materials. Limitations on arsenic exposure would control effects of arsenic solubility, bioavailability, and toxicity on environmental receptors. Additional detail on the studies that have been conducted on arsenic stability in mill wastes and the design responses to these studies is found in Section 13.9 of the Feasibility Report (M3 2021).
von Lindern, Ian (Founder, Terragraphics International Foundation)	17436	25	Careful concurrent review of the evolution of the New MoDPRO2 Alternative using the 2014/2019/2021 M3 Feasibility Study documents and the subsequent MoDPRO and MoDPRO2 Alternative modifications, indicates that the Forest Service should be more diligent and forthcoming in the SDEIS, and in informing the public regarding difficulties with toxic soluble arsenic in the TSF discharge.	WTR	The arsenic contained within tailings would be managed within containment facilities that would inhibit environmental exposure during operations and long term with impermeable liners and clean cover materials. Limitations on arsenic exposure would control effects of arsenic solubility, bioavailability, and toxicity on environmental receptors. Additional detail

			<p>The brief mention of HAC (Hot Arsenic Cure) in the SDEIS apparently parrots a two paragraph statement in Section 2.2.5 Tailings Arsenic Management, in Perpetua, October 2021, STIBNITE GOLD PROJECT: REFINED PROPOSED ACTION – MoDPRO2. In short, Perpetua acknowledges that 2018 testing showed a substantial amount of amorphous (unstable) arsenic compounds formed in the POX would result in elevated soluble arsenic in POX waste and the tailings leachate. These levels may not meet water quality standards during post closure, necessitating long-term water treatment, even with the MoDPRO improvements.</p> <p>Perpetua then asserts that, based on mid-2020 tests, the new Alternative MoDPRO2 will address the soluble arsenic detoxification problems as follows: “During the initial years of operation, Perpetua Resources would monitor levels of soluble arsenic in the tailings. If soluble arsenic levels were higher than anticipated, Perpetua Resources would treat the oxidized concentrate with hot arsenic cure (HAC) prior to neutralization.”</p> <p>Repetition of a single unsupported sentence in serial reports does not constitute reliability in the assertion that the HAC is a catch-all solution for the arsenic instability problems in the largest on-site discharge.</p>		on the studies that have been conducted on arsenic stability in mill wastes and the design responses to these studies is found in Section 13.9 of the Feasibility Report (M3 2021).
von Lindern, Ian (Founder, Terragraphics International Foundation)	17436	26	<p>Although the documents show Midas was aware of, and actively investigated these problems in 2018, the Forest Service was either unaware of, or chose to ignore, these concerns in the DEIS and, subsequently, in the SDEIS. The only public disclosures regarding arsenic detoxification difficulties prior to the DEIS were the two brief references to arsenic behavior in wastes in the 2019 Feasibility Study noted and copied in full in the original DEIS comments.</p> <p>The 2021 Technical Feasibility Study disclosure to Investors provided the details of the tests that indicated conditions necessary to capture precious metals in the POX/CN/Detox circuit, resulted in arsenic instability downstream of the autoclaves; and largely labile, pentavalent As being discharged to the TSF.</p> <p>The following are the first and last paragraphs of Section 13.9.4 Arsenic Stability Investigation (2020) of the 2021 Technical Feasibility Study summarizing the problem, investigations and conclusions: The stability of arsenic was a concern flowing out of the 2018 metallurgical product environmental geochemical results. A test work program was initiated at SGS commencing April 2020 to examine where arsenic destabilization occurred.</p> <p>Section 13.9.4.7 Arsenic Deportment Across Metallurgical Circuit concludes: Arsenic destabilization appears to be an inevitable outcome of raising the pH of the POX residues for the recovery of gold employing the cyanide carbon-in-leach step. The destabilization of arsenic does not seem to be reversible at pH values above neutral and only appears to be arrested when the pH is reduced to approximately 8.5 in Cyanide Detox. Arsenic is expected to leach from POX residues and report to the process liquors. The only sink for aqueous arsenic is in the pore water within the tailings facility and in the autoclave and neutralization circuits where arsenic containing process water is employed in the feed repulp, reagent make up and quench water (emphasis added).</p>	WTR	The arsenic contained within tailings would be managed within containment facilities that would inhibit environmental exposure during operations and long term with impermeable liners and clean cover materials. Limitations on arsenic exposure would control effects of arsenic solubility, bioavailability, and toxicity on environmental receptors. Additional detail on the studies that have been conducted on arsenic stability in mill wastes and the design responses to these studies is found in Section 13.9 of the Feasibility Report (M3 2021).
von Lindern, Ian (Founder, Terragraphics International Foundation)	17436	28	<p>Finally, the stabilization results referenced in the Feasibility Study are based on Synthetic Precipitation Leachate Procedure (SPLP) test results. SPLP is commonly used to simulate the effect of acid rain on land-disposed waste (e.g., land application or unlined landfills) where leaching to groundwater is a concern. The SPLP test is not a regulatory test, and concentrations are generally compared to drinking water standards (i.e., 0.01 mg/l for As). The 2021 Technical FS leachate studies refer to “acceptably low SPLP concentrations of As (<2 mg/L).” The justification for this SPLP “cut off” level is unknown as it is 200 times the drinking water standard.</p> <p>Because these wastes are to be disposed in a lined and covered TSF landfill, the Toxic Characteristic Leachate Procedure (TCLP) is a more appropriate test, and that most often cited in reviews of arsenic stabilization (Nazari, et al (2017). TCLP is a regulatory test and the standards are generally 100 times the drinking water standard. The TCLP procedure generally shows considerably greater concentrations of arsenic than the SPLP. The use of SPLP in the earlier studies suggest that Midas was concerned with</p>	WTR	<p>The arsenic contained within tailings would be managed within containment facilities that would inhibit environmental exposure during operations and long term with impermeable liners and clean cover materials. Limitations on arsenic exposure would control effects of arsenic solubility, bioavailability, and toxicity on environmental receptors. Additional detail on the studies that have been conducted on arsenic stability in mill wastes and the design responses to these studies is found in Section 13.9 of the Feasibility Report (M3 2021).</p> <p>The TCLP test is only applicable to regulated hazardous wastes for disposal purposes. Mill tailings are not regulated as hazardous wastes so TCLP testing is not applicable. SPLP and WMWT was therefore used to help characterize the waste materials.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			disposal of the arsenic subject to meteoric waters. MoDPRO2 changed the TSF configuration to a geo-synthetic cover. As a result, the Forest Service should not rely on SPLP test results in evaluating arsenic stability, and should consider the Perpetua's alleged capacity to stabilize amorphous arsenic in the POX/CN/Detox is unproven.		
von Lindern, Ian (Founder, Terragraphics International Foundation)	17436	29	TSF Leak Detection and Treatment: The concern with appropriate leachate testing was exacerbated with the Idaho mining industry's successful lobbying effort to modify the IDEQ CN waste disposal rules. At the time Midas was conducting arsenic stabilization investigations, the Idaho CN rules required double-lining, and leachate collection and treatment for the TSF. These rules were amended by the Idaho State legislature and as noted in the SDEIS, the TSF will not require double lining. Leak detection will be commenced in groundwater monitoring as opposed to between the liners, and feasibility of timely seepage collection/treatment is unlikely. This rule change increases the urgency for reliable arsenic stabilization alternatives.	WTR	Comment noted. Statement of position. No response required.
von Lindern, Ian (Founder, Terragraphics International Foundation)	17436	30	Summary of Arsenic Tailings Concerns: Numerous tests conducted prior to the DEIS indicated significant arsenic instability associated with POX/CN/Detox proposed discharges to the TSF. These instabilities were not disclosed to, or were ignored by, the Forest Service in the DEIS. Midas Gold performed an assessment of arsenic stability in 2020 and alleged that the HAC had been developed to address this problem in the new 2021 MoDPRO2 Alternative. Examination of the studies, however, show these were based on three tests of a single ore concentrate, were significantly diluted with pre-POX flotation tailings, and relied on an inappropriate leachate procedure. The DEIS and SDEIS failed to mention or consider these uncertainties and shortcomings. Simultaneously, IDEQ cyanide disposal rules were amended, relieving the SGP of double lining the TSF. Leakage from the TSF will likely be undetectable in any way that supports corrective actions. The Forest Service should not accept Perpetua's assertions that arsenic in the TSF discharges can be stabilized, and consider an Alternative that does not require on-site treatment and disposal of thermally treated arsenic.	WTR	The arsenic contained within tailings would be managed within containment facilities that would inhibit environmental exposure during operations and long term with impermeable liners and clean cover materials. Limitations on arsenic exposure would control effects of arsenic solubility, bioavailability, and toxicity on environmental receptors. Additional detail on the studies that have been conducted on arsenic stability in mill wastes and the design responses to these studies is found in Section 13.9 of the Feasibility Report (M3 2021).
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	18	For example, degraded water quality is a major concern both in the short and long term. Water quality effects will depend significantly on the CWA permitting for the mine site. But Perpetua and the Forest Service have failed to disclose in any detail what types of CWA permits will be issued for which point sources, where those permitted point sources will be located, which standards will apply to them, and other important factors.	WTR	As described in SDEIS Section 3.9.3, the State of Idaho implements the CWA permitting through the IDEQ. The water quality effects analysis in the EIS incorporates the reasonably foreseeable outcome that the Project operates under Idaho regulations and operational permit requirements. Attainment of these requirements is achieved through use of on-site water treatment facilities which are described in the EIS with regard to their design and process plus their influent and effluent volumes and chemistries in Section 4.9.2.2.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	25	Temporal data is also limited. As discussed below, the SDEIS fails to address the potential long-term impacts of water treatment at the West End Pit and the Tailings Storage Facility, which may continue for an indefinite period of time.	WTR	SDEIS Section 4.9.2.2 describes the water treatment process, treatment volumes and treatment duration. Water treatment is predicted to be necessary until reclamation and closure activities reduce outflow from the tailings storage facility to near-zero. This discharge condition is expected to be reached after approximately 40 years of tailings draindown. Based on modeling for the project, the West end Pit is not expected to have the potential to overflow for 40 years, monitoring will occur to determine if the pit will overflow and corrective actions will be utilized as necessary.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	30	In February 2022, the Corps adopted the pre-2015 WOTUS rule, which no longer categorically excludes ephemeral features as jurisdictional waters and the General Condition 23(d) Stream Mitigation threshold changed to all losses of stream bed that exceed 3/100-acre. Although impact analysis is completed and jurisdictional review is underway, it isn't clear how this review will address impacts to WOTUS identified in the SDEIS. Would this increase the impacted acreage if adopted? The results of this review including (identification of acreage, full analysis and disclosure of impacts) need to be addressed in a revised SDEIS.	WTR	As described in SDEIS Sections 3.11.4.3 and 3.11.4.4, wetlands are delineated per USACE methodology involving hydrophytic vegetation, hydric soil, and wetland hydrology while streams and riparian areas are delineated along reaches with perennial and intermittent flow based on distances from ordinary high water marks (forested areas) or flood prone widths (non-forested areas). The effects analysis presented in SDEIS Section 4.11.2.2 is based on effects to those delineated wetlands, streams, and riparian areas. The determination of which of these areas are jurisdictional under the WOTUS rule is the purview of the USACE who will determine the level of impact and mitigation required through their Clean Water Action Section 404 permitting process. While the Forest Service does not determine the level of impact and mitigation requirement, a Project decision would require fulfillment of the mitigation requirement as determined by the USACE.

Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	78	<p>A. Groundwater and surface water hydrology</p> <p>1. The MODPRO2 model needs additional clarification, testing, and potential improvement before predictions of groundwater and streamflow impacts can be made and conclusions can be formed. There remain unaddressed comments from the MODPRO modeling that apply to the MODPRO2 modeling, as well as new comments on the MODPRO2 groundwater modeling effort. The MODPRO2 model needs additional clarification, testing, and potential improvement before predictions of groundwater and streamflow impacts can be made and conclusions can be formed. These concerns include spatial calibration bias, a model domain that is too close to areas of impacts, model layering that may be inadequate to estimate vertical hydraulic gradients, model layer geometry that may adversely affect model results, and a lack of testing major geologic structures in the area, to name a few. These concerns should be addressed and potentially corrected to improve upon the model's ability to predict impacts.</p> <p>One of the largest concerns of the MODPRO2 modeling is the lack of correlation of what the model results mean in terms of potential impacts to sensitive ecosystems. The modeling results are presented in terms of a) drawdown of the water table during and after mining at discrete times, b) modeled predictions of the recovery of streamflow after mining, and c) percentage of abundance of particles (flow paths) from the three pits (two backfilled and one pit lake) that will report to various stretches of different streams, creeks, and rivers. Furthermore, drawdown impacts are only shown for a minimum evaluation of the 10-foot drawdown contour, and sensitive ecosystems may be impacted at levels below this threshold. The model predicted impacts should be equated to volumes of impacted groundwater and rates of impacted groundwater movement to sensitive downstream ecosystems, rather than only in the context of groundwater and surface water drawdown and recovery. The general impact of modifying the model to address the comments in this letter could potentially change model predictions such as:</p> <ul style="list-style-type: none"> ● Groundwater flow directions and interaction with surface water during and after mining, ● Estimated depth to groundwater and impacts of groundwater mounding beneath or within facilities and generated geochemistry, and ● Estimates of groundwater discharge to the open pits which could, in turn, influence estimates of ultimate pit lake level, the amount of and impacts from groundwater pumping for makeup water, and the geochemistry of seepage during and after mining. <p>The SDEIS must take a hard look at the potential impacts to surface and groundwater hydrology, and associated impacts. More detailed comments are provided in Semmens (2022).</p>	WTR	<p>The groundwater flow model was evaluated by the Forest Service and deemed suitable for use in the impact analysis. Limitations and uncertainties associated with model predictions are described in SDEIS Section 4.8.2.2. Mitigation measures to address these limitations and uncertainties plus account for ongoing additional data collection are described in SDEIS Section 4.8.3.</p> <p>The impact analysis utilizes the results of the numerical groundwater flow model to predict Project dewatering pumping requirements, the lateral extent of drawdown associated with this groundwater pumping, and the time for water levels to recover following the cessation of pumping. Limitations in pumping performance and response data are addressed via monitoring requirements and model updates that incorporate monitoring results.</p> <p>A change in groundwater elevations of 10 feet or more was selected for identifying areas of potential drawdown impacts. This threshold was established based on the fact that natural fluctuations in water levels, particularly in fractured rock aquifers, commonly exceed 10 feet. Drawdowns of less than 10 feet are not considered because these changes probably would not be measurable or distinguishable from natural seasonal or annual variations in groundwater levels. In addition, the 10-foot drawdown cone has been used as the threshold for defining the potential drawdown effect in numerous mining EIS documents for over 25 years. The Forest Service acknowledges that numerical models could be used to provide predictions of drawdown of less than 10 feet and that drawdown of less than 10 feet could significantly impact flow in some perennial seeps, springs, and streams. However, the extent of the model domain and the lack of detailed hydrogeologic data outside the mine exploration areas make smaller scale drawdown predictions in these areas unreasonable.</p>
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	79	<p>2. The water-quantity related modeling is substantively flawed and must be addressed to provide an accurate analysis of potential impacts.</p> <p>There was no adoption of science-based widely-available forecasts of climate change in the MWB and SWWB models and simulations that looked out as much as 100 +/- years into the future and informed the Modflow 6 simulations. Thus, there is 100 +/- years worth of bias built into not only these outputs but also in the Modflow 6 simulation outputs, because MWB model outputs of runoff and recharge, used as Modflow 6 inputs and SWWB inputs are based on MWB climate inputs of temperature and total precipitation – with snowfall derived, presumably, from these two time series that start nearly 120 years ago. The temperature and snowfall biases that likely result are unacceptable. The precipitation bias that likely results is small and perhaps acceptable. What was done should not be characterized as the “best available science”.</p> <p>Uncertainty, while apparently considered in the SWWB/GoldSim model, has not been addressed for the MWB and Modflow 6 models (which together form the SHSM model couplet). The apparent uncertainty analysis conducted for the SWWB/GoldSim model is identified with that particular adjective because the lack of documentation on what was done, how it was done and why it was done leave this reviewer with more questions than answers on the matter. The Forest Service should stipulate that Perpetua apply the tools in the GoldSim uncertainty analysis toolkit to all elements in the SWWB/GoldSim model that can</p>	WTR	<p>Quantitative incorporation of climate change forecasts is outside the scope of this analysis. The effects of climate change are described qualitatively in SDEIS Section 4.4.2.2.</p> <p>Sensitivity analyses were performed on the SHSM model regarding model inputs and assumptions related to climate change that were material to the predictions of dewatering pumping rates, the extent of dewatering drawdown, and groundwater recovery following the cessation of pumping. These predictions were utilized to assess Project effects on groundwater quantity. Uncertainty around these predictions was described in Section 4.8.2.2 with monitoring and modeling update requirements described in Section 4.8.3.</p> <p>Model documentation including sensitivity analyses used to develop the Water Quantity Specialist Report and the SDEIS are provided in their reference sections and were provided by Perpetua to the Forest Service.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>potentially affect surface water and groundwater quantity demands and the timing of those demands, and to adequately document and interpret the actions taken and the results.</p> <p>It appears as though the Water Quantity Specialist Report (USDA Forest Service 2022b) and SDEIS (USDA Forest Service, 2022a) authors did not have the resources necessary to comprehend and understand the MWB model development and simulations, nor the SWWB model development and simulations, based on the very limited coverage given to each in the SDEIS and Water Quantity Specialist Report. This is most regrettable and of dire consequence for the Forest Service’s assessment of hydrological environmental impacts and of environmental impacts that stem from hydrosystem impacts. The Forest Service needs to request all model supporting documents from Perpetua and hire independent third party hydrologists with very strong backgrounds in numerical modeling to reanalyze MWB and SWWB model results. The focus needs to be on the question of whether the assumptions, data selection, and conceptualizations used in development and application of these models were conservative with respect to the environmental impacts that depend on the predicted changes to the hydrologic system.</p> <p>The validity of the MWB model has not been established. Similarly, the validity of the apparent 1-way coupling between the MWB model and the Modflow 6 model has not been established. The validity and logic for the use of monthly averaging for climatic data inputs in both the MWB and SWWB models has not been established. The Forest Service should require that Perpetua establish validity in both of these regards.</p> <p>There is considerable groundwater model domain with projected future peak drawdowns less than 10 feet that exist outside of the 10-ft drawdown contour used to define what the proponent feels are the areas of certain drawdown, or level of drawdown that is significant in comparison with their estimate (method unknown) of uncertainty. The areas of lesser drawdown, which include wetlands and groundwater-dependent ecosystems (GDEs), are not adequately considered. Also, it is not clear in the SDEIS water-related sections that water resource monitoring will actually occur both outside of and within this artificial boundary. Much greater emphasis needs to be placed on monitoring drawdowns less than 10 feet and areas of impact outside of this artificial boundary.</p> <p>Forecasts of future stream flow using the Modflow 6 model need to be based on probable future climate conditions, not on improbable past or present climate conditions. Only then can the associated simulations correctly inform assessments of water quality, ecosystems, fish species and other water-dependent environmental impacts. It is possible that the impacts on stream flow from the combination of mine-related surface water and groundwater abstractions and probable future climate change will leave stream water quality in a state that is inferior to that projected under the no-action alternative. This needs to be addressed by the proponent.</p> <p>Please see more extensive details on these issues in Schlinger (2023).</p>		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	80	<p>B. Geochemistry</p> <p>1. The geochemical testing results and modeling efforts are flawed and inadequate, and will likely underestimate impacts.</p> <p>The selection of samples for geochemical testing did not consider hydrothermal alteration, which can substantially affect contaminant leaching and acid generation potential. Failing to use geochemical test units within each lithology means that the testing results are most likely not representative of the range of leachate chemistry that will develop at the mine. In addition, the volumes of each subgroup within a lithology with different leaching characteristics is not known and cannot be applied to the block model and the SWWC model to more accurately estimate site water quality.</p> <p>The methods used to estimate neutralization potential (NP) will likely overestimate NP in the long term. Overestimating NP will make it appear as if fewer samples and waste types are potentially acid generating (PAG). If more mined material is PAG, additional mitigation measures will be needed to prevent the formation of acid drainage from new mining activity.</p>	WTR	<p>Phases 1 and 2 of the geochemical characterization program tested samples from each of the lithologies substantially present in the mined materials as described in SDEIS 3.9.4.2. This testing included multiple static tests for each substantially present lithology to cover the range of geochemical conditions present in that lithology. The geochemical test data and historical site observations support that conclusion that acidic drainage would not be expected to form because the neutralization potential present exceeds acid generating potential. Kinetic tests were run more than 100 weeks and exhaustion of their acid generation potential was confirmed prior to ending each test. The use of first flush kinetic test leaching data is described in SDEIS Section 3.9.4.2 with potential implications for predictive modeling described in SDEIS Section 4.9.2.4.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>Much uncertainty exists about whether the newly mined materials will produce acid and therefore leach higher contaminant concentrations over the long term. Although the kinetic tests were conducted for more than 100 weeks in many cases, rocks in the deposits could take even longer to form acidic drainage. The depletion rates of NP and acid production potential are similar, which makes it difficult to predict which will “win out” in the long run. Because the wastes will exist at the site in perpetuity, long-term leachate production is important, and conservative estimates should be used to design effective mitigation measures.</p> <p>Source terms were created using leaching rates and concentrations from long- and short-term leach tests, respectively. They are expressed as rates (in mg/kg/week) and are one of the most important inputs to the SWWC model for predicting water quality. The “first flush” of contaminants is released during the early weeks of humidity cell testing, but rates from those times were not used to develop source terms. Instead, lower average “steady-state” rates from later times in testing were used. The first flush of contaminants from mined materials will occur when weathered wastes and ore are flooded (e.g., in flooded pits) and when weathered wastes and ore are wetted from storm events or snowmelt, especially after a previous dry period. Such conditions will exist at the Stibnite site in waste and ore stockpiles, backfilled pits, pit walls, and in the TSF buttress/embankment. Because the first-flush rates have been ignored, the source terms for development rock and ore will underestimate the release of contaminants from these mine facilities during operations and closure/post-closure.</p> <p>Source terms were developed using the designations of PAG versus non-PAG and waste versus ore for a given deposit and lithology. However, these distinctions do not result in a meaningful difference in source term values for arsenic and antimony, which are two of the mine-related contaminants of highest concern (that is, source term values are very similar for PAG versus non-PAG and for waste versus ore). Source terms for the SWWC model need to be thoroughly reexamined in a revised SDEIS.</p>		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	82	<p>1. The site-wide water chemistry model is inadequate and underestimates impacts. As detailed in Maest (2022), the site-wide water chemistry (SWWC) model relies on inputs from the geochemical characterization program, source terms, the water balance model, and water treatment plant (WTP) effluent quality to predict water quality resulting from development of the Stibnite Gold Project. The model predicts average annual and average monthly concentrations for site water quality and uses average precipitation, runoff, and infiltration without considering climate change. The extensive use of averages will underestimate potential maximum concentrations that will require treatment or management.</p> <p>The SWWC does not evaluate the effects of ammonia or selenium. Ammonia will result from blasting of the open pits, and selenium can be leached from mined materials. The effluent discharge permit (IPDES) for release of treated water to Meadow Creek may require monitoring and permit limits for both of these mine-related contaminants. The treatment evaluation does not consider the removal of ammonia or selenium.</p> <p>The SWWC model includes individual conceptual models for the pits and the TSF but does not include an overall conceptual model for the entire site. The SWWC model also does not consider the stream sediment (surface water-stream sediment) or food-chain (sediment-macroinvertebrates/periphyton-fish) pathways, and no monitoring of these environmental media (sediment, macroinvertebrate, periphyton contaminant content) is proposed.</p> <p>Although the movement of contaminants from the TSF and the pits is considered in the water balance model, the future use of groundwater for drinking water has been excluded from consideration in the SDEIS. The potential for domestic groundwater use in the future cannot be discounted. The Forest Service is obligated to ensure that the proposed mine plan is in compliance with all applicable state and federal laws.</p> <p>The SWWC and the underlying water balance model do not consider climate change. The past precipitation and temperature record is included in water balance calculations, but future climate projects are not included in any evaluations for the SDEIS. Because the mine life is proposed to be 20 years (including construction, operation, closure, and reclamation), TSF seepage is predicted to last for 40</p>	WTR	<p>Climate change was not explicitly incorporated into numerical water chemistry modeling. SDEIS Section 4.4.2.2 qualitatively describes climate change implications for water quality.</p> <p>Project effects on selenium and ammonia concentrations are described in SDEIS Section 4.9.2.2.</p> <p>Project component conceptual models are incorporated into the overall conceptual model depicted in SDEIS Figure 4.9-1. Surface water chemistry analysis incorporates sediment control measures as described in Chapter 2 of the EIS to limit effects of Project-related sediment.</p> <p>Drinking water was not considered as a potential exposure pathway in the assessment of human health effects as described in SDEIS, however the drinking water standard of 0.010 ppm As is the lowest applicable criteria for the project as the South Fork is designated as a drinking water source. S Section 4.18.2.2. However, the water quality analysis compares predicted groundwater analyte concentrations to drinking water standards and existing conditions which do not currently meet drinking water standards. The SDEIS notes that under the current condition, water treatment is required for use of groundwater as a drinking water source.</p> <p>The coprecipitation water treatment technologies proposed by the Project have been used effectively for mine water treatment for more than 20 years. Therefore, there is a reasonable expectation that they would be able to achieve water treatment objectives.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>years, and post-closure and active management of the site will be needed in perpetuity, it is unacceptable that climate change has not been incorporated into the predictions for the proposed project. Climate change must be incorporated into all water balance estimates and the SWWC model, and made available for public review in a revised SDEIS. The need for perpetual capture and treatment of mine-influenced water should also be evaluated in a revised SDEIS.</p> <p>The mine water treatment approaches proposed have not been evaluated using laboratory bench studies, and the desk study that was performed used outdated references whose conclusions have been contradicted by more recent studies. These many shortcomings indicate that the SWWC model and associated studies need to be thoroughly reevaluated in a revised SDEIS.</p>		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	83	<p>2. Surface water quality standards must be protective of aquatic life. The lack of aquatic life criteria for antimony is concerning. The SDEIS must consider the potential impacts of antimony on aquatic life. As described in more detail in Maest (2022), a chronic aquatic life guideline for antimony should be incorporated to provide adequate protections for fish and other aquatic life. The selenium standard used to compare to predicted surface water concentrations in the SWWC model may not reflect the most updated approach used by the U.S. EPA that includes monitoring of not only water but also aquatic biota.</p>	WTR	<p>An antimony standard of 0.0052 mg/L applied for surface water was based on a drinking water standard. This value is lower than the 0.190 mg/L standard for aquatic life.</p> <p>As described in SDEIS Table 3.9-1, the selenium standard utilized is the EPA freshwater aquatic life criteria.</p>
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	84	<p>3. Groundwater quality protections must account for public use.</p> <p>Existing groundwater under the TSF buttress/embankment does not exceed arsenic or antimony standards, but all predicted groundwater arsenic and antimony concentrations are higher than background values and Idaho groundwater standards, showing that groundwater quality in this location is expected to worsen as a result of the project. The use of groundwater at the site as a drinking water resource in the future should require that the project cannot worsen groundwater quality. The arsenic groundwater standard of 0.05 mg/L does not reflect the current federal drinking water standard and should be updated for future groundwater use. The SDEIS seems to imply that the proposed mine plan does not need to consider human health concerns related to groundwater pollution at SGP. According to the SDEIS (ES-15), There are no active domestic groundwater wells used for residential drinking water within 15 miles of the SGP. Because groundwater is not currently used as a public drinking water source at the SGP and is assumed to be unlikely to be used as a drinking water source in the future, the Agency for Toxic Substances and Disease Registry Public Health Assessment conducted for the existing mine site eliminated the groundwater as drinking water pathway from consideration as a public health concern (ATSDR 2003). Yet the cited report is 20 years old, and the ATSDR was completing an assessment of the site to fulfill its congressional mandate for preparing a public health assessment within one year of EPA proposing a site to the National Priority List (Superfund). In contrast, the proposed SGP is a new mine plan subject to applicable groundwater quality standards. The SDEIS must consider groundwater as a potential future drinking water pathway for the purposes of the proposed SGP. Mine operations, closure and post-closure are predicted to affect area resources for the next 60 years (20 years of operations and 40 years of water treatment), with ongoing groundwater impacts continuing post-closure. It is reasonable to expect that groundwater resources in the area may be needed for drinking water resources in the next 20-60+ years, given the increase in population, demands on water resources and the effects of climate change. According to IDEQ, ground water supplies drinking water to 95% of Idaho citizens. As Idaho's population grows, so does the need for clean, usable groundwater, with recent reports pointing to Idaho's population boom putting demands on domestic water supplies.</p>	WTR	<p>The exposure analysis conducted in ATSDR 2003 remains valid as the condition of the site relative to domestic use has not changed.</p> <p>SDEIS Figures 3.9-20 and 3.9-21 show the baseline distribution of antimony and arsenic in the Meadow Creek area groundwater that would be affected by the TSF Embankment and Buttress. While the majority of these monitoring well results exhibit antimony concentrations below the drinking water standard, most monitoring well results show an exceedance of the arsenic drinking water standard. Therefore, the area currently does not appear to be a viable source of drinking water without use of water treatment to remove arsenic. Figure 4.9-20 shows the predicted spread of groundwater from under the TSF facility over a 100-year timeframe. The spread of the plume is contained within a rugged, mountainous area administered by the Forest Service. Installing culinary water wells within this area in the future is not reasonably foreseeable.</p>
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	85	<p>4. The SDEIS must take a hard look at potential impacts to groundwater and provide adequate data, including maps of existing and predicted groundwater plumes. The SDEIS fails to provide sufficient information to determine the extent of groundwater pollution from the proposed SGP, detailed information about applicable groundwater standards and compliance points, and whether groundwater standards will be met. The SDEIS must include appropriate modeling, with detailed maps to document the existing and anticipated groundwater plumes at the site, similar to those done for the East Smoky Canyon EIS. Without this information, it is impossible to determine the geographic extent of groundwater pollution.</p>	WTR	<p>In the Project area, topography focuses groundwater flows along narrow drainage bottoms that also host streams at their ground surfaces. Areas of groundwater affected by historical and proposed operations are elongated along these valley bottoms.</p> <p>SDEIS Figures 3.9-20 and 3.9-21 show the locations where monitoring well observations indicate the presence of arsenic and antimony concentrations above water quality standards as part of existing conditions. These locations are associated spatially with the valley bottoms and their surface streams.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
					SDEIS Figure 4.9-20 illustrates the source and destination of groundwater movement from mine facilities through groundwater to the surface water drainage areas. The affected groundwater areas are located between the mine pit source areas and the indicated receiving surface waters.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	86	<p>5. Water quality impacts may be underestimated due to location of assessment nodes. Surface water quality predictions were made at assessment nodes downstream of project facilities (pits, DRSFs, and the TSF). The predicted changes at the assessment nodes account for both impacts due to project facilities and dilution in the streams between the project discharges and the assessment node. This could result in an under prediction of water quality impacts since stream chemistry between the project discharges and the assessment node could be greater than that predicted at the node. For example, assessment node YP-SR-4 appears to be about 2000 feet downstream of the Yellow Pine pit and therefore is not necessarily representative of impacts to the EFSFSR closer to the pit. This could imply that a mixing (dilution) zone would be authorized, which would not typically be available in an impaired situation such as the current situation at the project site. As such, the SDEIS may be underestimating water quality impacts associated with the project. The SDEIS needs to analyze the potential impacts to surface water, which requires identifying water quality impacts at the point of greatest potential impact. The SDEIS should provide data to demonstrate that the proposed assessment points accurately represent this.</p> <p>The SDEIS must also provide details on the groundwater points of compliance, with separate points of compliance for the Sugar Creek and the EFSFSR watersheds. There is no reason to believe that groundwater containing high levels of arsenic won't move under the perched water table created for the Stibnite Lake, through the Yellow Pine backfill and emerge at the first downstream gaining reach of the EFSFSR. Without this information, it is impossible for the public to determine the extent of potential impacts to groundwater and potentially surface water resources.</p>	WTR	<p>The SDEIS analysis provides predictions for surface water chemistry at locations established by Midas Gold/Perpetua Resources, where surface samples have been collected for analysis to establish existing conditions. Utilizing model results for these locations facilitates a comparison of predicted Project effects to existing conditions. The location of assessment node YP-SR-4 is appropriate because it is downstream of the SGP and upstream of the next contributing stream (Sugar Creek) to the EFSFSR.</p> <p>The Forest Service is not establishing points of compliance for surface water or groundwater as that compliance is the purview of IDEQ as described in SDEIS Section 3.9.3. Likewise, the Forest Service is not establishing mixing zones related to points of compliance. However, the Forest Service is evaluating the effect of the Project on surface water and groundwater chemistry via a comparison of predicted water chemistry to observed existing conditions and numerical water quality standards. The impacts of the SGP on groundwater chemistry within the boundaries of the mine area and downgradient of the mine area are discussed starting on page 4-243. The particle tracking modeling showed the potential extent of groundwater flow downgradient of the mine area over 100 years.</p>
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	87	<p>6. A TMDL is required for 303(d) listed streams.</p> <p>All IDEQ-inventoried water bodies at the proposed mine site (except for West End Creek) are listed under Section 303(d) of the federal CWA as “impaired” due to water quality. The causes for listing of these waters are associated with elevated concentrations of arsenic, antimony, and mercury. Each of the 303(d)-listed water bodies has designated beneficial uses of “cold water communities,” “salmonid spawning,” and “primary contact recreation,” and all (except Sugar Creek) have designated beneficial uses of “drinking water supply.”</p> <p>Sugar Creek is 303(d) listed category 5 for arsenic (PCR) and mercury (COLD, PCR, SS). (SDEIS, Table 6-16). The SDEIS predicts an “increase in arsenic concentrations (0.013 mg/L to 0.014 mg/L),” and an “increase in mercury concentrations (6 ng/L to 8 ng/L) in Sugar Creek in association with the closure of the Bailey Tunnel and the removal of its contributions to Sugar Creek chemistry plus the arrival of groundwater outflow from the West End pit lake in the post-closure period (SRK 2021a).” (WQ specialist report, p. 155)</p> <p>As described in the SDEIS (p. 4-225), water quality in the West End pit lake will exceed water quality standards for antimony, arsenic and mercury concentrations throughout the operating and closure period. Mine-impacted groundwater flowing from the West End pit lake is hydrologically connected to surface water in Sugar Creek.142 As a result, an NPDES Permit is required for discharges of groundwater to surface water. Furthermore, a TMDL is required to address the contribution of arsenic and mercury to Sugar Creek, a 303(d) limited stream for those parameters. A TMDL should be completed for all 303(d) listed streams at the Mine Site, including, but not limited to the East Fork SFSR (1st, 2nd and 3rd order streams) (See Table 3.9-17).</p> <p>The SDEIS also identifies numerous 303(d) limited streams along the access road and utility corridor. IDEQ lists Johnson Creek on its 303(d) list of impaired waters “due to temperature, which routinely exceeds the 10 degrees Celsius (50 degrees Fahrenheit) guideline for bull trout spawning in the summer.” (SDEIS, p. 3-488) Other 303(d) limited streams along the utility corridor are identified in Table 4.9-23. (P. 4-265). Many of these streams are identified as impaired for temperature, sediment,</p>	WTR	<p>Establishment of TMDLs is the purview of IDEQ as described in SDEIS Section 3.9.3. The Forest Service is evaluating the effect of the Project on surface water and groundwater chemistry via a comparison of predicted water chemistry to observed existing conditions and numerical water quality standards.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			and phosphorus. A TMDL should be completed for all 303(d) listed streams along the access road and utility corridor, and where TMDLs are already developed, the SDEIS must demonstrate that the impacts from proposed mine activities will not result in further impairment. The SDEIS must take a hard look at the potential direct, indirect and cumulative impacts of the proposed impacts (including vegetation clearing, sediment loading, etc.). These impacts must be quantified, and climate change must be taken into account. It is also inadequate to assert that BMPs or specific design requirements will adequately address the potential impacts, without providing data to support that assertion. A qualitative assessment is inadequate to understand the potential impacts to these resources. Please see additional detailed comments on this issue from Newberry (2022).		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	89	<p>8. The SDEIS fails to provide baseline data to characterize organic carbon or quantify the increase in organic carbon from the sewage treatment plant and its potential impacts.</p> <p>The SDEIS (4-220) predicts 25,000 - 50,000 gallons per day of discharge from the sewage treatment plant to the EFSFSR. However, it fails to provide detailed information about the sewage treatment plant, describe the potential effluent concentrations, or analyze the potential effects of these discharges to surface waters. The SDEIS fails to provide current baseline data to characterize organic carbon in area streams. (Water Specialist Report p. 67) It relies on another study (Holloway 2017) in which water quality data was collected in 2015 - baseline data which is now seven years old and outdated. The SDEIS (p. 452) predicts increases in organic carbon loading rates in the East Fork SFSR, but it hasn't modeled potential surface water quality changes resulting from the wastewater treatment plant discharges. • The SDEIS must provide current baseline data to characterize organic carbon in area streams, and quantify the potential impacts to surface water from the sewage water treatment plant, including the potential for increased algae. It should also analyze the cumulative effects of increased carbon and other pollutants from the sewage treatment plant on the EFSFSR and associated aquatic life, in association with the other potential impacts, such as predicted increases in stream temperature associated with climate change, increases in mercury from air deposition, and other potential impacts. The SDEIS should also consider the risks of a sewage spill from operations and/or transport of sewage materials. For example, the Pogo gold mine in Alaska has experienced repeated spills of raw sewage when transferring sewage to vacuum trucks, and as a result of a myriad of problems at the Water Treatment Plant, resulting in violations of fecal coliform in nearby surface waters.</p>	WTR	<p>Baseline organic carbon data are described in SDEIS Section 3.9.4.4. As described in that section, the poorly developed soils and sparse vegetation in the drainage area are associated with low organic carbon concentrations in surface water. The general soil conditions in place at the time that the data were collected remain in place. Therefore, it is reasonable to conclude that surface water organic carbon concentrations have remained low.</p> <p>The effects of treated wastewater on surface water organic carbon concentrations are described qualitatively in SDEIS Section 4.9.2.2. The quantitative changes in organic carbon concentrations would be dictated by IPDES permit limitations. The IPDES permit limitations combined with the relatively low volume of discharge compared to receiving stream flow led to the conclusion that changes in surface water organic carbon concentrations would be incrementally small compared to existing conditions.</p> <p>As described in the SDEIS, sewage systems would be equipped with waste containment and runoff control structures to prevent escape of untreated sewage to surface water.</p>
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	90	<p>9. The Forest Service should not approve any operations that increase water pollution, especially in impaired waters.</p> <p>In addition, to the increased pollution in water bodies in (6), there are additional areas where the SDEIS predicts that water quality will exceed standards or worsen existing conditions as a result of mining activities.</p> <ul style="list-style-type: none"> ○ The SDEIS (p. 4-192) predicts that subsurface infiltration from the TSF embankment and buttress will mix with the alluvial groundwater under the facility footprint, resulting in a groundwater chemistry with antimony and arsenic concentrations above the strictest potentially applied water quality standards. Infiltration from the unlined TSF buttress is predicted to have a more notable effect on groundwater analyte concentrations. Specifically, mixing of infiltrated leachate with previously unimpacted alluvial groundwater is predicted to increase antimony and arsenic groundwater concentrations above existing conditions and groundwater standards. (SDEIS, p. 4-243) ○ The SDEIS predicts that a small portion of the groundwater flow from the Yellow Pine pit backfill would reach groundwater to the west of the EFSFSR channel, where antimony and arsenic concentrations are currently below standards, and could cause an increase in groundwater concentrations for those two pollutants. (p. 4-244). ○ Immediately downstream of the West End pit on West End Creek at node YP-T-6 (above the confluence with Sugar Creek), predicted surface water mercury concentrations are an order of magnitude higher than existing conditions during the operating period due to the observed West End concentrations. (SDEIS, p. 4-251) 	WTR	<p>The Forest Service analysis of water quality utilizes a comparison of predicted water chemistry to observed existing conditions to identify effects of the Project on water quality. As described in SDEIS Section 3.9.3, regulatory authority regarding the Clean Water Act is the purview of IDEQ which will determine whether the Project can be permitted under its IPDES and cyanidation permits. The Forest Service analyses of Project water quality did not conclude that the Project would not comply with applicable state and federal requirements or Idaho antidegradation policy.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>○ Similarly, downstream of the project on the EFSFSR at node YP-SR-2 (below the confluence with Sugar Creek), mercury concentrations are expected to increase in surface water due to variability in water treatment, although remain below standards.</p> <p>○ The West End pit lake water quality concentrations are predicted to exceed potentially applicable water quality standards for antimony, arsenic, and mercury throughout the operating and closure period (Figure 4.9-14 and Table 4.9-12). The SDEIS (p. 4-348) also predicts that water quality standards for these contaminants will be exceeded permanently post-closure, and that the pit lake would not be reclaimed or restored and would therefore have impacts on fish in perpetuity. The SDEIS (P. 4-243) also finds that “Where the local groundwater has not been previously impacted, the groundwater interactions with inundated backfill pore water and the West End pit lake would have the potential to increase groundwater concentrations for antimony and arsenic to levels above groundwater standards.”</p> <p>The SDEIS fails to demonstrate that the proposed plan will comply with applicable water quality standards. The SDEIS also predicts uncertainty about the potential overflow of the pit lake during high flow conditions, and describes the potential for the use of either or both surface water diversions or the use of a mobile water treatment plant if water levels reach a threshold level. (SDEIS, p. 2-87) It states that lake levels will be monitored after closure, as specified in the EMMP, but no specific reference or details to this are found in the 2021 EMMP.</p> <p>The plan must demonstrate that the pit lake and a potential overflow of the pit lake will comply with applicable standards, and not defer to some future options without sufficient detail to demonstrate viability. An overflow of the pit lake will most likely be in response to a storm event, in which there may be inadequate time to mobilize a water treatment plant. Further, the diversions are expected to be decommissioned after mine closure, which appears to conflict with their proposed use in the event of an overflow. The SDEIS concludes that “Formation of the West End pit lake acts to permanently raise temperatures compared to existing conditions in the stream segment immediately below that area which receives discharges of groundwater that has interacted with the pit lake.” (p. 4-275) The additional pollution loading caused by the Project, including allowing discharges before the required TMDL is produced and waste load and load allocations are implemented, violates the Forest Service’s duties to “minimize adverse environmental impacts on National Forest surface resources.” 36 C.F.R. § 228.8. “The operator also has a separate regulatory obligation to ‘take all practicable measures to maintain and protect fisheries and wildlife habitat which may be affected by the operations.’ 36 C.F.R. § 228.8(e).” <i>Rock Creek All. v. Forest Serv.</i>, 703 F. Supp. 2d 1152, 1164 (D. Mont. 2010) (mine approval violated Organic Act and 228 regulations by failing to protect water quality and fisheries). “Under the Organic Act the Forest Service must . . . require [the project applicant] to take all practicable measures to maintain and protect fisheries and wildlife habitat.” <i>Id.</i> at 1170. The CWA, Organic Act, and agency regulations preclude the Forest Service from approving aspects of a mining operation that would violate federal or state water quality standards. “Under the Clean Water Act Section 313, the Forest Service cannot authorize mining operations that do not comply with state and federal water quality regulations, including a state’s antidegradation policy. 33 U.S.C. § 1323(a). <i>Save Our Cabinets v. U.S. Dep’t of Agric.</i>, 254 F. Supp. 3d 1241, 1249 (D. Mont. 2017) (Forest Service approval of mining project violated duties under CWA and Organic Act to ensure compliance with water quality standards). See also <i>Hells Canyon Pres. Council v. Haines</i>, 2006 WL2252554, *4-5 (D. Or. 2006) (Forest Service mine approvals violated state CWA standards).</p> <p>The Organic Act mandates the same compliance, as the Part 228 regulations “further require that mining operators comply with applicable state and federal water quality standards including the Clean Water Act; [and] take all practicable measures to maintain and protect fisheries and wildlife habitat.” <i>Save Our Cabinets</i>, 254 F. Supp. 3d at 1250. The 228 regulations require that the operator submit sufficient information to enable the agency to ensure that the Project will comply with all applicable state and federal requirements to protect water quality and fisheries. See 36 C.F.R. §§ 228.4(c)(3), 228.8(b), 228.8(e). The SDEIS does not show, or properly analyze, that all aspects of the project will fully protect “fisheries and wildlife habitat” and comply with all CWA standards and requirements.</p>

Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	91	<p>10. The SDEIS must provide clarity on applicable standards and criteria</p> <p>The SDEIS refers to “potentially applicable standards” and “potentially applicable criteria in many locations throughout the document. The Forest Service must demonstrate through the NEPA process that the proposed mine plan will be in compliance with all state and federal laws, yet it is impossible for the public to determine what standards will apply, and whether the proposed mine plan will be in compliance. Cyanide leach mining operations frequently result in water quality impacts that were not predicted during the permitting process. It is essential that the NEPA process provide detailed information and take a hard look at the potential impacts of the proposed project on surface and groundwater quality</p>	WTR	<p>State and federal agencies with regulatory authority over the SGP have been extensively coordinated with regarding the content of the SDEIS. The application of water quality standards is within the purview of multiple regulatory agencies as described in SDEIS Section 3.9.3. Therefore, the potential standards that could be applied by those agencies are aggregated to determine the most stringent potential standard as presented in SDEIS Table 3.9-1.</p> <p>Uncertainty in the prediction of Project water quality effects is described in SDEIS Section 4.9.2.4 with mitigation measures targeted at reducing uncertainty described in SDEIS Section 4.9.3.</p>
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	92	<p>11. The SDEIS fails to provide current baseline data to characterize water quality in streams adjacent to proposed access roads, utility corridors and off-site facilities that have the potential to be impacted by SGP activities</p> <p>According to the Water Quality Specialist Report, the Surface Water Quality Baseline Study (HDR 2017) did not include sample locations outside of the proposed SGP. However, streams adjacent to proposed access roads, utility corridors, and off-site facilities have the potential to be impacted by these SGP activities. According to the report, “The types of impacts that could occur are usually described qualitatively because little is known about the existing water quality of these streams.” (Water Quality Specialist Report, p. 72). Instead, the SDEIS refers to IDEQ’s 303(d) water quality monitoring program, and provides general descriptions of area streams based on whether they fully support beneficial uses, don’t support beneficial uses or weren’t assessed. (Figure 6-14). NEPA requires current and detailed baseline data to characterize all streams and other water bodies that have the potential to be impacted by SGP activities, including access roads and utility corridors.</p> <p>Without this data, it is impossible to determine the potential impacts associated with the proposed project.</p>	WTR	<p>NEPA does not require collection of new baseline data if there already is sufficient information available for the lead agency to make an informed decision. The SDEIS utilizes IDEQ’s 303(d) water quality monitoring to describe the existing conditions for surface waters that would be crossed by access roads. Access roads, utility improvements, and off-site facilities would be constructed and utilized per design features and Forest Service requirements to minimize the effects on surface water quality. Potential impacts of off-site roads and utility corridors that might be used for the Project are described on page 4-262 of the SDEIS.</p>
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	94	<p>13. The SDEIS must consider surface water & groundwater quality cumulative effects</p> <p>It should be noted that both the liner and cover systems installed on the TSF and TSF buttress are engineered materials with finite life times. It is reasonably foreseeable that they will eventually degrade and fail at some point in the future. The magnitude and duration of contaminant release at that time is unknown, however it would certainly have the potential to adversely affect both surface water and groundwater. The SDEIS must take a hard look at the potential for long-term, cumulative effects to water quality, and analyze potential mitigation measures, including pumpback wells, or other mitigation options. Furthermore, the SDEIS Section 2.4.7.4 states that “A low permeability geosynthetic liner would be incorporated into the cover over the entire surface of the backfilled Yellow Pine pit, including the reconstructed channel floodplain corridor to reduce the infiltration of meteoric water into backfill material, which could dewater the restored stream channel and result in additional metal leaching from the underlying backfill.” This is not a realistic long-term mitigation measure. The SDEIS fails to provide detailed information about the liner, or examples of where this has been successfully conducted on other mine sites at this elevation and subject to flash flooding, plant roots, and other impacts that would compromise the liner integrity. Further, the SDEIS provides no detailed information about how this system would be maintained in perpetuity. The SDEIS must analyze the direct, indirect and cumulative impacts associated with the inevitable failures in the liner system over time, including the cumulative effects of climate change. For example, the 500-year storm event that occurred in Montana in 2022, which resulted in massive flooding, destruction of roads, rerouting of rivers and streams, and other substantial impacts.</p>	WTR	<p>The EIS has been revised to include examples of liner placement over mine facilities. An associated mitigation measure has been added to Section 4.9.3 of the Final EIS.</p>
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	104	<p>a. Habitat impairments are significant enough to consider Stibnite among the U.S.’s most contaminated sites</p> <p>Contaminants associated with historic mining at Stibnite resulted in heavy metals and cyanide contamination in area soils, groundwater, seeps, sediments, and thus surface waters (USEPA 2020). An initial assessment conducted by the U.S. Environmental Protection Agency (USEPA) in 1985</p>	WTR	<p>SDEIS Section 4.12.2.2 describes effects of sediment on fish populations and on productivity of macroinvertebrates and other fish prey.</p> <p>Sediment conditions were initially evaluated in the 1990s as summarized by URS 2000 then revisited by the USGS in their 2015 investigation. A summary of these findings was added to the EIS. Recent activities conducted under the No Action Alternative and proposed activities</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>determined habitat impairments in the watershed were significant enough to consider it among the U.S.'s most contaminated sites in (USEPA 2020). Despite significant restoration and some cleanup efforts, the site remains contaminated and an eligible Superfund site. Moreover, numerous streams in the East Fork drainage of the South Fork Salmon River (EFSFSR) as well as the South Fork Salmon River (SFSR) exceed Idaho standards for drinking water and aquatic habitat, and thereby are considered 'impaired.' Exceedances are documented for arsenic, antimony, mercury, temperature, and sediment in watersheds and subwatersheds that will be impacted by mining (IDeq 2018). While the SDEIS indicates that some water quality will be improved by treatment associated with the proposed Stibnite mining project, ground and surface water flows are poorly characterized and treatment is neither sufficiently described nor tested for effectiveness.</p> <p>Maest (2020) states: "The food chain/dietary pathway for fish (contaminated stream sediment to macroinvertebrates to fish) was not considered in the DEIS conceptual models, in the examination of existing conditions, or in current or future modeling efforts. It was also not considered when evaluating potential environmental improvements from planned legacy cleanup or mitigation measures. No information is provided in the DEIS on stream sediment metal/metalloid concentrations"; and "A reliable evaluation of the potential effects of the mine cannot be completed without site-specific information on chemical speciation and the toxicity of antimony to fish populations". Further, Maest discloses that sediment arsenic concentrations exceed the probable effects level (PEL) by up to 400 times, and sediment mercury concentrations exceed the PEL by up to 50 times. The food chain/dietary pathway for arsenic has been shown to adversely affect salmonids in laboratory experiments and at locations in Montana and Idaho, yet it was completely ignored in the DEIS". These same comments apply to the SDEIS as well (Maest 2022).</p> <p>Stream sediment chemistry is an important source of analyzing contaminant loading to fish. The food chain/dietary pathway for fish, starting with contaminated stream sediment, was not considered in the SDEIS conceptual models for existing conditions or current and future modeling efforts. Excluding stream sediment from the contaminant pathway analysis is a major, fundamental flaw with the conceptual model for this site, ignoring best available science, biological opinions, and U.S. FWS and NMFS Recovery Plans for ESA-listed salmonids.</p> <p>The SDEIS does show limited sediment quality data from five stream locations taken in June 2016. These samples showed that at three of five locations for arsenic, and four of five locations for mercury, levels exceeded Canadian guidelines for the protection of aquatic life. Although the U.S. does not have established sediment guidelines, Canadian guidelines provide a useful reference for sediment concentration guidelines to protect aquatic life. The food chain/dietary pathway for arsenic has been shown to adversely affect salmonids in laboratory experiments and using stream sediment from mined areas in Montana and Idaho. Yet, the SDEIS completely ignored stream sediment data.</p> <p>A conceptual model showing the food chain/dietary pathway for contaminant impacts to fish from consuming macroinvertebrates residing in contaminated stream sediment is needed. More sediment sampling is needed, and the results should be included in the design of conceptual models, mitigation, and clean-up measures.</p>		<p>under the Action Alternatives are designed to reduce the total load and metal concentrations of sediments in the Project area.</p>

Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	105	<p>c. Temporal variability of metal contaminants</p> <p>One of the most distinctive features of site surface water quality is the temporal variability in concentrations associated with stream hydrographs. Consideration of temporal variability is especially important at sites affected by mine contaminants, such as streams in the Stibnite area. Although the Forest Service and plan proponent analyzed surface water samples, surface water monitoring was not frequent enough or well-timed with snowmelt to identify temporal changes and maximum concentrations. Knowing maximum concentrations of contaminants is important in understanding the potential for acute short-term toxicity to aquatic biota and for assessing the effectiveness of clean-up and mitigation measures. Therefore, weekly, daily, or ideally hourly sampling is needed during or shortly after spring freshet and summer thunderstorms to estimate potential maximum concentrations and to use in the calibration of the inputs for water quality models. These should be presented in a supplemental SDEIS.</p>	WTR	<p>SDEIS Section 3.9.4.4 describes the observed temporal variability in total and dissolved surface water concentrations associated with existing conditions. This variability is most notable with respect to total mercury concentrations which are influenced by amounts of particulate matter in stream flow, and Arsenic under baseflow conditions.</p> <p>The observed surface water chemistry variability associated with variability in surface flow rates was incorporated into the surface water chemistry predictions presented in SDEIS Section 4.9.2.2 in Figures 4.9-22 through 4.9-25.</p>
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	106	<p>d. Antimony speciation and food chain pathway</p> <p>The toxicity of arsenic and antimony to humans via drinking water and to aquatic biota is highly dependent on their chemical form (chemical speciation) in surface water and groundwater. The SDEIS did not analyze any water samples for chemical speciation. Essentially no information is available in the literature on the potential food chain/dietary pathway for antimony, which is one of the most important contaminants from legacy and proposed mining activity. Further, little fundamental information is available on the aquatic toxicity of antimony, and arsenic cannot be used as a surrogate. Neither the state of Idaho nor the federal government have established antimony criteria for the protection of aquatic life. A reliable evaluation of the potential effects of the mine cannot be completed without site-specific information on chemical speciation and the toxicity of antimony to resident fish populations. Site-specific toxicity testing should be conducted using clean sediment and sediment with a range of elevated antimony concentrations. Such work is especially important for understanding the effectiveness of promised legacy cleanup measures.</p>	WTR	<p>SDEIS Section 3.9.4.4 describes antimony as present primarily in its more oxidized species (i.e., Sb(V)). Because Project contributions of antimony would be associated with leaching of oxidized mine materials, it is likely that associated antimony species would also primarily be Sb(V).</p>
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	108	<p>f. Water chemistry impact predictions consider unjustifiably limited parameters of concern</p> <p>The SDEIS qualitatively evaluates impacts to fish from potential increases in concentrations of a few metals (mainly arsenic, copper, mercury, and antimony). Those described impacts are largely minimized in the document. Copper is considered amongst the most toxic elements to all aquatic life with increases of 2-20 parts per billion imparting deleterious indirect impacts on salmonid survival. Mercury biomagnifies with increasing trophic levels, ultimately leading to grave concerns for human health. Information regarding toxicological impacts of both arsenic and antimony are insufficient in the literature at large, and virtually non-existent for the Stibnite Gold project area.</p>	WTR	<p>The constituents considered for the water quality analysis are presented in SDEIS Section 4.9.2.2 with quantitative results presented in Figures 4.9-22 through 4.9-25 and Tables 4.9-18 through 4.9-21. The effects of the Project on arsenic, antimony, and mercury concentrations are also described in the narrative. Copper concentrations are not predicted to differ from existing conditions. Arsenic and antimony concentrations are based on federal drinking water criteria and the toxicological rationale for setting those standards. Observed ecological effects of arsenic and antimony take place at higher concentrations than the drinking water standards as observed in the development of aquatic life standards for those constituents. The potential effects associated with mercury concentrations are related to methylmercury which is described in Section 4.9.2.2.</p>
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	109	<p>g. Multiple other contaminants of significant concern to salmonids and other aquatic life receive no consideration in the SDEIS</p> <p>In addition to impacts of several other existing contaminants at the site most likely related to historic mining activities were overlooked or not considered at all (aluminum, cadmium, iron, manganese, selenium, and zinc; see Zamzow 2020). Other metals are likely to increase as a result of Stibnite Gold Project development, but given the certainty of increases in these metals, some potential impacts of lesser-considered metals are described below. In particular, because they biomagnify, mercury and selenium should both be considered in much more depth than they are in the SDEIS. Moreover, information regarding toxicity (direct, indirect, lethal, and/or sublethal) of antimony is widely lacking.158 Given the near certainty of increases in antimony concentrations resulting from Stibnite Mine development, laboratory toxicity testing (including laboratory tests using site-specific waters) should be required prior to permitting.</p> <p>Maest (2020) concludes that little information on the toxicity of antimony to aquatic biota; no site-specific information on antimony or arsenic toxicity to resident and protected fish, macroinvertebrate,</p>	WTR	<p>Predicted concentrations of aluminum, cadmium, iron, manganese, selenium, and zinc are presented in SDEIS Tables 4.9-18 through 4.9-21. Concentrations of these constituents are predicted to remain below regulatory standards and to vary little from existing conditions.</p>

			and aquatic plant populations; and no information is provided on the relationship between fish life cycles and temporal variability of arsenic, antimony, mercury, or any other analytes in site surface waters. No information is provided on the exposure to fish from arsenic, antimony, mercury, or other contaminants via the dietary pathway (sediment-macroinvertebrate-fish). This pathway has been shown to cause adverse effects to salmonids at mine sites in Idaho and Montana.”		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	111	SDEIS Figure 3.9-1 describes the surface water quality analysis area to include streams and lakes located in the 22 sub-watersheds that encompass the proposed mine site, access roads, transmission lines, and off-site facilities within the East Fork and South Fork Salmon River watersheds. Yet Chapter 4 only analyzes effects to water quality at the mine site area. The SDEIS does not analyze consequences to the surface water quality analysis area downstream and outside of the Stibnite Gold Project area (increased temperatures, spill risk, metals concentrations).	WTR	SDEIS Section 4.9.2.2 describes the effects of spill risks on surface waters outside of the mine area. Activity outside the mine area (i.e., power transmission and road access) are not expected to modify stream temperatures and metal concentrations at these locations.
Idaho Regulatory Agencies	17718	121	Need to update to Idaho DEQ 2022 Integrated Report, which has received EPA approval	WTR	Edit has been made.

Idaho Regulatory Agencies	17718	125	1. Update footnote 2 to “2022 Integrated Report”	WTR	Edit has been made.
Idaho Regulatory Agencies	17718	143	This is not the most current flow diagram which was submitted with the IPDES Individual Industrial Permit application (please contact Perpetua/Brown and Caldwell for the most current diagram).	WTR	The flow diagram has been updated.
Idaho Regulatory Agencies	17718	144	According to SRK_2021_Stibnite_ModPRO2_SWWC_AP_20211020_FNL provided by Perpetua/Brown and Caldwell provided as part of the Individual Industrial Permit application (data provided by SRK Consulting)	WTR	The flow diagram has been updated.
Idaho Regulatory Agencies	17718	120	Statement “There are no active domestic groundwater wells used for residential drinking water within 15 miles...” may need to be verified. IDWR has several domestic wells on record in Yellow Pine. Furthermore, IDAPA 58.01.02.130.10 S-23: East Fork of the South Fork Salmon River – source to mouth has a designated domestic water supply beneficial use. that are not MIDAS GOLD Inc wells. (i.e., Well #442288.,355654, 359550. 370682, 370681, 432827, 286123, 355655, 286122, 436188, 286170, 418314, 370681, 370682, 359550, 355654. 370682, 442288,).	WTR	The text has been revised to indicate that potable water wells in Yellow Pine are located more than 8 miles from the Project area in a downgradient direction in terms of the EFSFSR watershed.
Idaho Regulatory Agencies	17718	77	The reference to SRK, 2021 is incorrect. The geologic map shown is from Stewart, et al, GEOLOGIC MAP OF THE STIBNITE QUADRANGLE, VALLEY COUNTY, IDAHO. SRK may have slightly modified it by adding the mineralized zones shown in red. But, that information is also not from SRK. Please correct.	WTR	Edit has been made.
Idaho Regulatory Agencies	17718	86	Why does water from the TSF Buttress, Pit backfill, and Development Rock percolate into the groundwater? Same question for the ore stockpiles? This schematic does not show any water treatment before going into groundwater.	WTR	The analysis presented in SDEIS Section 4.9.2.2 assumes that some percolation from the mined materials would occur because while measures (e.g., geosynthetic covers) would be used to minimize the percolation, some percolation would still occur. Percolation from the base of these facilities would not be able to be intercepted for water treatment.
Idaho Regulatory Agencies	17718	87	"The pit lake is not expected to overflow to the surface." The stated reference could not be found. What is this expectation based on? The numerical groundwater flow model is probably cannot be used as an infallible predictive model. This needs a better explanation, and it needs to assume that overflow is possible, as that is what "not expected" suggests. How will an overflow be dealt with?	WTR	The reference regarding the prediction that the West End Pit lake would not overflow to surface is the Water Management Plan. This citation has been added to the EIS.

Idaho Regulatory Agencies	17718	88	In all graphs, the correct citation is IDAPA 58.01.11	WTR	Edit has been made.
Idaho Regulatory Agencies	17718	89	In all graphs, the correct citation is IDAPA 58.01.11	WTR	Edit has been made.
Idaho Regulatory Agencies	17718	90	In all graphs, the correct citation is IDAPA 58.01.11	WTR	Edit has been made.
Idaho Regulatory Agencies	17718	91	"However, there are still several constituents that are predicted to be elevated above existing conditions and/or applicable water quality standards in surface water or groundwater throughout the entire 100-year model-simulated post closure period, attributable to a combination of existing conditions and mine-impacted waters. Due to these predicted water quality changes, water treatment of several mine-related discharges would be required to maintain the long-term productivity of water resources both within and downstream of the mine area until facility seepage collection plus cover and liner systems effectively abate discharge of mine-impacted water to the environment (over approximately 40 years)." Comment: based on the information presented in this paragraph, it is assumed that facility seepage would end at 40 years, but the model states 100 years. These statements are in conflict. Please rewrite.	WTR	As stated, there would be some constituents in exceedance of water standards throughout the 100 year prediction based primarily on the existing conditions at the site and not reduced below those standards by Project-related activity. No revision has been made to the section.
Idaho Regulatory Agencies	17718	156	Similar what you included under Federal Laws on pg 3-104, add a paragraph about the instream flow water rights held by the Idaho Water Resource Board under State and Local Laws	WTR	The requested paragraph from the Water Resources Specialist Report has been added to the EIS text.
Idaho Regulatory Agencies	17718	157	Current text: "Water rights associated with mining projects are protected from forfeiture under Idaho Code 42-223(11)." As written the statement is too absolute. Soften the statement and/or add further language from 42-223 (11) for context.	WTR	The requested revision has been made. "Water rights associated with mining projects are protected from forfeiture for nonuse under Idaho Code 42-233(11), provided the water right owner has maintained the property and mineral rights for potential future mineral production."
Idaho Regulatory Agencies	17718	158	Current text: "Storage of water is not subordinated ...as storage not more than a 24-hour water supply for any beneficial use." Add a sentence that Perpetua is proposing mitigation for their proposed storage ponds.	WTR	Revision made. "Mitigation for stored water would be addressed via IDWR's decision on Perpetua's proposal and water rights application."
Idaho Regulatory Agencies	17718	159	Current text: "The maximum diversion rate under existing and proposed surface water rights is 4.05 cfs," Isn't the maximum diversion rate 9.6 cfs? And 4 cfs (one significant figure) is a "typical rate"? Please clarify.	WTR	The clarification has been added that a 4 cfs diversion would be the expected diversion under normal operating conditions when there would not be a demand for additional make-up water.

Benjamin Davenport, Executive Director, Idaho Mining Association	18777	8	<p>V. The Clarity and Consistency of the Impact Analysis Can be Improved in the Final EIS</p> <p>IMA was glad to see that your October 21, 2022 Dear Reader Letter announcing the availability of the SDEIS described Perpetua’s Modified Mine Plan (MMP) as “reducing surface disturbance and anticipated environmental impacts.” However, we are concerned that the SDEIS does not convey this same message because it does not clearly or consistently describe the MMP’s environmental improvements compared to the Plan of Operations/Proposed Action (the ModPRO) evaluated in the 2020 Draft EIS.</p> <p>Fortunately, the data presented in the SDEIS (especially in the figures and tables) present a clear picture that the MMP will substantially improve water quality in the project area and downstream from the project and restore miles of stream and fish habitat. In the Final EIS, the Forest Service needs to edit the document to improve the consistency and clarity of the text so that it more clearly matches the data shown in the figures and the tables – especially in Section 4.9 on Surface Water and Groundwater Quality.</p>	WTR	The Final EIS includes revision of the executive summary to reflect the water quality effects of the Project.
Benjamin Davenport, Executive Director, Idaho Mining Association	18777	9	<p>A. The Executive Summary Does Not Accurately Summarize the SDEIS Findings</p> <p>Because most members of the public will not have time to read the entire SDEIS, they will probably rely on the Executive Summary to understand the SGP and the associated benefits and environmental impacts. Unfortunately, as written, the Executive Summary devotes more effort to discussing the adverse impacts rather than highlighting the water quality improvements and habitat restoration that would result from the MMP. The Executive Summary needs to give equal weight to the impacts and benefits associated with the MMP – especially the proposed restoration activities to address problems stemming from the legacy mine waste features.</p> <p>It is curious that the Executive Summary downplays these benefits when the Environmental Consequences chapter of the SDEIS contains abundant and detailed analyses and data that clearly show</p>	WTR	<p>The Final EIS includes revision of the executive summary to reflect the water quality effects of the Project.</p> <p>The acknowledgement of new sources of mine waste material has been retained as components of the proposed Project and the analysis of their effects on water quality as described in SDEIS Section 4.9.2.2.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>water quality and fish and stream habitat improvements. The Executive Summary in the Final EIS needs to describe these beneficial impacts more clearly so they are consistent with the data presented in the SDEIS.</p> <p>The Executive Summary in the Final EIS also needs to mention two significant environmental restoration measures in the MMP, Stibnite Lake and Blowout Creek, both of which are omitted from the Executive Summary in the SDEIS. The MMP's addition of Stibnite Lake is a significant environmental enhancement compared to the ModPRO analyzed in the Draft EIS. Perpetua is proposing to construct this lake in the backfilled Yellow Pine Pit to mitigate the loss of the Yellow Pine pit lake fish habitat area and to minimize stream temperature fluctuations. This project refinement is in response to the public comments received on the Draft EIS that voiced concerns about the loss of lake habitat for fish and fluctuating stream temperatures. The Executive Summary in the Final EIS should describe the beneficial impacts associated with Stibnite Lake and give credit to Perpetua for listening to and acting upon the public comments on the Draft EIS to improve the project.</p> <p>Also, the Executive Summary in the Final EIS needs to acknowledge the reclamation activities planned for Blowout Creek, which is currently a major source of sedimentation into the Yellow Pine Pit and the East Fork of the South Fork of the Salmon River (EFSFSR). The earthworks and revegetation restoration work in Blowout Creek that are part of the MMP will substantially eliminate this major sedimentation impact.</p> <p>The Executive Summary discusses water quality improvements in a very confusing and misleading way. Page ES-15/16 states:</p> <p>The MMP would improve some of the existing water quality conditions observed in Meadow Creek and the East Fork SFSR by removing and repurposing legacy mine wastes. However, the 2021 MMP would have direct permanent impacts on water quality, as it would contribute new sources of mine waste material to the East Fork SFSR drainage¹².</p> <p>As written, the second sentence negates the first sentence leaving the reader to wonder whether there will be net water quality improvements. At the very least, this paragraph needs to have a third sentence that explains the many state-of-the-art environmental protection measures and mine waste management design features that will prevent, limit, or mitigate impacts from project mine wastes.</p> <p>The Surface Water and Groundwater Quality section in the Executive Summary does a poor job of clearly explaining that the Site Wide Water Chemistry (SWWC) predictive modeling results for the downgradient prediction node at YP-SR-2 show water quality improvements during and after mining. Despite the fact that Figures 4.9-21 and 4.9-25 are easy to understand and clearly document that the MMP will improve water quality at YP-SR-2, the Executive Summary in the SDEIS never mentions these figures or quantifies the water quality improvements shown in these figures. The Executive Summary in the Final EIS needs to explicitly state that the SGP will achieve significant reductions in arsenic levels (40 percent) and antimony levels (58 percent) as predicted at YP-SR-2 compared to baseline conditions. The Executive Summary would be greatly enhanced by including Figure 4.9-21. If including a figure is inconsistent with the Forest Service's editorial guidelines for an Executive Summary, the Executive Summary in the Final EIS should at least reference Figures 4.9-21.</p> <p>It is very important for all sections of the Final EIS to present a transparent and balanced discussion of the data in the SDEIS and the Specialist Reports that discloses both the impacts and benefits associated with the SGP. Both the Executive Summary and the Final EIS should give equitable treatment to the positive and the negative impacts. Based on the Executive Summary's emphasis on the impacts and minimization of the project benefits, it appears that the Forest Service is reluctant to highlight the environmental benefits (especially the water quality improvements) that will result from the remediation activities integral to the MMP. This seems odd because the Forest Service should be eager to find ways to improve the environmental conditions in the Payette and Boise National Forests – especially projects where there is a private-sector entity like Perpetua that is proposing to make the substantial investment needed to improve the environment.</p>		

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>IMA understands that the Forest Service cannot give a full-throated endorsement of the SGP and must remain neutral during the NEPA process. But maintaining neutrality demands adherence to the facts and a full and balanced disclosure of both the positive and negative impacts associated with a proposed action. There are abundant facts presented in the SDEIS and the Specialist Reports that document the beneficial impacts as well as the unavoidable or residual adverse impacts that would result from the MMP.</p> <p>In preparing the Final EIS, the Forest Service has the opportunity to present the data described in the SDEIS in a more balanced way that does not emphasize the adverse impacts while subordinating the beneficial impacts. This “balancing act” is largely an editing exercise to use the information in the SDEIS to discuss the spectrum of impacts associated with the SGP and to eliminate any internally inconsistent statements in the document. By editing the document in this manner, it will be easier to read and more useful to the public.</p>		
Benjamin Davenport, Executive Director, Idaho Mining Association	18777	10	<p>B. Section 4.9 Could be Improved by Editing it for Consistency</p> <p>IMA had to re-read Section 4.9 a couple of times before we were able to understand the water quality impacts discussion because it is not written in a way that is easy to understand. In fact, the discussion was very hard to follow until we saw Figure 4.9-21 “Locations for Surface Water Chemistry Predictions Stibnite Gold Project” on Page 4-246. This figure clearly and succinctly shows that the Site Wide Water Chemistry (SWWC) predictive model predicts the MMP will significantly reduce the concentration of arsenic and antimony in streams in the project area compared to the existing baseline levels of these metals. The most important data shown on Figure 4.9-21 are for the downstream prediction node, YP-SR-2, which is located downgradient of the mine facilities, below the confluence of Sugar Creek and the EFSFSR.</p> <p>Unfortunately, the SDEIS does not do a good job of explaining the importance of the modeling results at this downgradient monitoring point. Despite the fact that Figure 4.9-21 presents a very useful and easy-to-understand synthesis of the SWWC predictive modeling results, the SDEIS glosses over this important finding and fails to capitalize on Figure 4.9-21 to explain the water quality improvements. Because these improvements are one of the main environmental accomplishments that would result from the MMP, it is important for the public to understand this predicted outcome. The Final EIS should highlight this finding and explain that improved water quality downgradient from the mine area is one of the most significant indications that the SGP will improve the environment.</p> <p>As an example of the less than ideal organization of Section 4.9, IMA, like all SDEIS readers, had to wade through 64 pages of Section 4.9 before getting to the essential information that the project will improve water quality downgradient from the site. This key finding should not be buried on the 64th page of Section 4.9. IMA urges the Forest Service to edit Section 4.9 in the Final EIS to make it more useful and easier to read by presenting a synthesis of the key findings at the beginning of this section.</p> <p>Additionally, Section 4.9 contains some internally inconsistent text that is puzzling and obscures the water quality improvements that will result from the SGP. Besides being confusing, the contradictory statements are problematic if they are read in a vacuum or if project opponents parse them out of the document and selectively use them to assert the project will not improve water quality. For example, the discussion on Page 4-251 of the SDEIS misrepresents the modeling results at YP-SR-2:</p> <p>“Downstream of the project on the East Fork SFSR at node YP-SR-2 (below the confluence with Sugar Creek), predicted surface water chemistry <i>is largely unchanged from existing conditions</i> with some variability in predicted antimony, arsenic, and mercury concentrations during the operating and initial closure period (Table 4.9-21 and Figure 4.9-25).” (italics added for emphasis, bold in the original.)</p> <p>IMA strenuously objects to characterizing a 40 percent reduction in arsenic concentrations and a 58 percent reduction in antimony levels compared to baseline conditions as “largely unchanged from existing conditions.” This discussion contradicts and is inconsistent with the data shown in Figure 4.9-21</p>	WTR	<p>The Final EIS includes revision of the executive summary and Section 4.9 to reflect the water quality effects of the Project.</p> <p>The summary of water quality effects appears in the Executive Summary and SDEIS Table 2.8-1. Section 4.9 is not intended to be a summary of water quality effects, but instead a description of the multiple analyses that developed estimates for geochemical source terms, solute leaching, and water flow that concluded with the water quality predictions presented in the tables and figures at the end of the section.</p> <p>The SDEIS water quality analysis is based on a comparison of predicted surface water and groundwater analyte concentrations to regulatory standards as described in Section 3.9 and Table 3.9-1. Implications associated with water quality on wetlands, fish, wildlife, and human health are described in the sections associated with those resources (Sections 4.11, 4.12, 4.13, and 4.18, respectively).</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>and the data shown in Figure 4.9-25 for the downstream monitoring point, YP-SR-2. Ignoring and/or mischaracterizing these significant water quality improvements is factually incorrect and misleading.</p> <p>Fortunately, other sections of the SDEIS present a more factually correct discussion of the water quality improvements resulting from the SGP. For example, Page 4-522 properly reveals the SGP will improve water quality:</p> <p>“Under the SGP operations and closure, water quality of surface flow departing from the Operations Area Boundary would be the same or better than existing baseline conditions; therefore, there would not be impacts to the quality of downstream waterways...”</p> <p>The Final EIS needs to eliminate contradictory statements and consistently describe the water quality improvements resulting from the SGP. A simple and efficient way to achieve the necessary consistency would be to repeatedly reference the results shown in Figures 4.9-21 and 4.9-25.</p> <p>The SDEIS repeatedly states that the ATSDR Public Health Assessment conducted for the existing mine site eliminated groundwater as a drinking water pathway from consideration as a public health concern. Consequently, the detailed groundwater quality discussion in Section 4.9 is not an impact analysis and is thus academic and misleading. The Final EIS should clarify that the groundwater modeling results are a model input and do not represent an impact to a human receptor because the area groundwater is not a source of drinking water. The Final EIS should also explain that because the area surface waters are the ecological receptors for groundwater, the SWWC model appropriately incorporates the groundwater quality modeling results.</p>		
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	4	Implementing effective monitoring, corrective actions, and addressing uncertainty for effects to stream temperature.	WTR	Comment noted. Statement of position. See responses regarding stream temperature for additional details.
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	5	Ensuring impacts from groundwater and surface water contaminants (e.g., mercury, methylmercury, arsenic, and antimony) are not underestimated when demonstrating compliance with the Clean Water Act and determining if additional mitigation measures for potential impacts are needed.	WTR	Comment noted. Statement of position. See responses regarding surface water and groundwater chemistry for additional details.
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	26	<p>Riparian Vegetation Zones</p> <p>The DSEIS includes a measure to establish 18-foot-wide vegetation zones consisting of willow, spruce, and other riparian species that effectively shade stream flows in the restored and native stream channels in the mine area. Studies over the years have shown that riparian vegetation located outside of an 18-foot buffer is a critical component of riparian vegetation stream shade production. That is, restored riparian buffer widths would need to be much wider than 18 feet to produce levels of stream shade that would result in the predicted post-closure stream temperature conditions illustrated in Figure 4.9-27. The DSEIS references to the Environmental Monitoring and Management Plan (EMMP) framework, however, specific actions were not provided that described how full potential stream shading from riparian vegetation within the Riparian Conservation Area will be achieved for riparian areas located outside of 18 feet from the stream.</p> <p>EPA recommends the FEIS include specific management and protection that will be implemented to ensure (shade producing) riparian vegetation is promoted outside of 18 feet from the stream. Describe the specific planned efforts to eliminate anthropogenic disturbance, and promotion of riparian restoration, within the entire riparian zone, including the “outer” riparian zone associated with stream shade production (i.e., outside of 18 feet from the stream).</p>	WTR	<p>Reclamation and closure activities associated with the zone outside of the 18-foot wide area are described in the Project's Reclamation and Closure Plan. Most of the restored stream channels would be meandering in nature resulting in wider zones of stream side restoration closer to 100-feet or more across as depicted in the Reclamation Closure Plan Figures 3-7, 3-8, and 3-9. In some instances (e.g., restoration of the lower reaches of Fiddle Creek), the stream channel would be more direct with a width of stream channel restoration area closer to the 18-foot wide area.</p> <p>Anthropogenic disturbance affecting restored or reclaimed areas would be subject to subsequent Forest Service review and permitting under NEPA.</p>
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	27	<p>Stream Temperature</p> <p>The DSEIS states that predicted long-term post-closure cool stream temperature conditions depend on the successful implementation of “the lined Stibnite Lake lacustrine feature above the cover of the Yellow Pine pit backfill to moderate maximum stream temperatures.”</p>	WTR	Sediment monitoring would be required per an approved Water Resources Monitoring Plan.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>“Cooling” temperature properties of this lake is dependent on lake water residence time and depth, both of which are impacted by upstream sediment delivery. That is, sediment transport into the lake can result in sediment deposition on the lake bottom, reducing the water depth, and subsequently decreasing the lake residence time. Specifically, it was reported that “about 90 percent of coarse-grained sediment derived from upgradient is deposited in the Yellow Pine pit” along with approximately 20 percent of the fine-grained sediment (<0.0625 millimeter in diameter), and “[t]hus, the Yellow Pine pit is an effective sediment trap for coarse-grained particles but does not have a long enough residence time to deposit the majority of the fine-grained sediment load.” In addition, “most of the sediment load discharged from the Meadow Creek reach is deposited in the Yellow Pine pit lake”.</p> <p>Unless otherwise determined through modeling analysis, it can be expected that these same sediment transport/deposition dynamics will occur with the created East Fork South Fork Salmon River (EFSFSR)/Stibnite Lake complex. In addition, this material also highlights the likely need to understand sediment loading and transport in the EFSFSR watershed to maintain the future Stibnite Lake attributes that lead to “cooling” water temperatures.</p> <p>Several potential sediment reduction and management measures are introduced on DSEIS page 4-274, and it is stated that the effectiveness of these measures will be evaluated through the EMMP. However, the EMMP does not provide specific examples on how current and future sediment loading is evaluated (i.e., status monitoring), as well as evaluate the effectiveness of the proposed actions to address any future sediment “issue” (i.e., effectiveness monitoring).</p> <p>EPA recommends the FEIS include implementation of detailed monitoring strategies that will: 1) monitor and quantify the sources and amount of sediment loading (including both chronic and episodic) entering the EFSFSR river system upstream of the Stibnite Lake; 2) evaluate the transport of both suspended and bedload transport in the stream network upstream of the Stibnite Lake; and 3) monitor sediment deposition and bathymetry conditions in Stibnite Lake. Information collected as part of this monitoring effort is necessary to: 1) determine if a problem exists associated with excessive sediment loading and/or deposition in Stibnite Lake, and 2) provide the necessary information to produce plans intended to adequately address any future corrective action to address excessive sediment loading and/or deposition in Stibnite Lake.</p> <p>EPA also recommends the FEIS include detailed corrective action strategies that outline actions to: 1) correct/eliminate any future “elevated” sediment sources (similar to what is proposed to excessive sediment from Blowout Creek²⁵); 2) correct/eliminate the transport of the bed load and “coarse” sediment load that has entered the river network; and 3) potential mitigation measures to address potential future “shallowing” of Stibnite Lake resulting from sediment deposition.</p>		
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	28	<p>Significant Temperature Mitigation Feature</p> <p>Figure 4.9-27 illustrates that the most significant temperature mitigation feature in the EFSFSR river watershed is located between the TSFB and the East Fork Meadow Creek (EFMC). Specifically, modeled stream temperatures post mine closure (i.e., end of year 27) decrease up to 7° C within this short reach, which results in lower temperature to continue downstream in the EFSFSR. The DSEIS later reports that without this upstream temperature reduction “stream temperatures downstream of the Yellow Pine pit area could also be greater than existing conditions.” The DSEIS lists several possible reasons for this “significant” stream cooling reach: 1) resumption of “baseline” cool groundwater discharge; 2) increase stream shade; and 3) underdrain flow from the TSF.</p> <p>It is unlikely that the first two factors outlined on page 4-271 are meaningful factors in the creation of the “significant” stream cooling zone between the TSFB and the EFMC. The dashed line in Figure 4.9-27 indicates that stream temperatures currently increase within this reach, indicating that “baseline” groundwater influences within this reach are likely a relatively minor factor towards the creation of the “significant” temperature reduction zone. Additionally, it is unlikely that increase shade within this reach will result in the “significant” stream cooling zone because stream shade does not “cool” a river/stream. Stream shade reduces the amount of solar heat load (i.e., sun light) from reaching the stream water, and</p>	WTR	<p>To clarify, the SDEIS does not describe vegetation as directly cooling the stream. It does note that vegetation shading along a stream can result in a cooler stream than would occur in the absence of vegetation.</p> <p>Uncertainties regarding the effects of vegetation shading on stream temperatures are described in SDEIS Section 4.9.2.4 with monitoring and associated mitigation for temperature effects described in SDEIS Section 4.9.3.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>this lower heat load can result in a gradual loss of heat energy (i.e., temperature reduction) through the relatively slow evaporation/convection processes.</p> <p>It is possible that cool underdrain flow from the TSF added into this stream reach could physically “dilute” the warm stream water advecting from upstream. The amount of cooling would be dependent on the volume and temperature of these underdrain inputs.</p> <p>EPA recommends the FEIS: 1) provide additional analysis describing the potential uncertainty that the “cooling” feature will function as predicted, 2) ensure proposed monitoring assesses if the “cooling” feature functions as predicted, and 3) include a description of potential mitigation/corrective actions if the “cooling” feature does not occur as expected.</p> <p>An acknowledgment of potential uncertainty of predicted ground water discharge volumes and “restored” shade conditions is on page 4-281. However, as described above, these two factors are unlikely a significant source of the cool water within the TSFB and the EFMC reach of Meadow Creek. The potential uncertainty associated with the predictions of the magnitude and duration of the cool underdrain flows were not provided in the DSEIS. Material presented on Page 2-56 indicates that these underdrain flows may be unavailable for stream cooling within this reach due to 1) the potential need for it to be treated prior to discharge into the stream; and/or 2) the potential need for it to be used as makeup water for the mill process. Thus, EPA recommends the FEIS include evaluations in this assessment that describe the potential uncertainty associated with the magnitude and duration of the predicted underdrain flows.</p> <p>The DSEIS does not discuss potential mitigation measures associated with a lower production and/or elevated temperatures of the expected underdrain flows discharging into the “significant” stream cooling zone between the TSFB and the EFMC. EPA recommends the FEIS include evaluations in this assessment that describe potential mitigation/corrective actions needed to address any loss or reduced effectiveness from the underdrain flows expected within this reach.</p>		
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	29	<p>Groundwater Analyte Concentrations</p> <p>The DSEIS indicates groundwater analyte concentrations beneath the mine site, particularly in the vicinity of the TSF, TSFB, Hangar Flats pit backfill, and Yellow Pine pit backfill are expected to increase in response to constituent leaching from development rock. Existing groundwater in those areas typically does not meet regulatory criteria for use as drinking water due primarily to arsenic and antimony concentrations.</p> <p>To adequately describe the nature and extent of additional groundwater contamination contributed by SGP, EPA recommends the FEIS include a summary that describes the magnitude of groundwater concentrations above current baseline conditions and the geographic extent (in feet) over which baseline concentrations are exceeded. Figures which depict the extent and magnitude of groundwater concentration changes in relation to mine facilities would be particularly helpful to disclose groundwater impacts.</p>	WTR	<p>The magnitude of potential increases in groundwater chemistry are based on the predictions for seepage from the TSF embankment and buttress (SDEIS Table 4.9-8) and from the development rock backfills in the Midnight, Hangar Flats, and Yellow Pine pits (SDEIS Tables 4.9-13,4.9-14, and 4.9-15).</p> <p>SDEIS Figure 4.9-20 illustrates the starting locations for groundwater affected by pit backfill or the West End Pit lake and the destination for that groundwater. The areal zone between the starting locations and the destinations represents the area where groundwater concentrations could be increased relative to existing conditions by the Project.</p>
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	30	<p>Surface Water Methylmercury (MeHg) Concentrations</p> <p>The DSEIS states “MeHg concentrations in SGP site streams are not appreciably different from those reported by the USGS nationwide study, and that historical mining activity in the analysis area has not increased MeHg concentrations above those observed at similar reference locations throughout the U.S.”</p> <p>It is accurate that the USGS nationwide study did not identify an increase in MeHg in basins containing mines; however, the FEIS will need to include a caveat that this study only included one sample location from Idaho, and that location was outside of the Stibnite study area. As such, the statement that mining activity has not increased MeHg above “similar reference locations” is inaccurate. Instead, EPA recommends the FEIS state that MeHg concentrations in the Stibnite area were similar to those observed in non-mining impacted watersheds throughout the US.</p>	WTR	<p>The note that the USGS study utilized one location in Idaho has been added to the text.</p> <p>Changes in the dissolved organic carbon are described in SDEIS Section 4.9.2.2 where the use of sewage water treatment systems would have the potential to result in a small incremental increase in organic carbon concentrations when operated in compliance with expected IPDES requirements.</p> <p>Average predicted sulfate concentrations in surface waters are similar to existing conditions with maximum predicted sulfate concentrations rising above those levels but to concentrations less than the 45.9 mg/L value reported for the national average in the USGS study.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			It is important when comparing MeHg concentrations to other areas that these be interpreted in the context of the dissolved organic carbon (DOC) and sulfate levels present. The national USGS study referred to includes measures of these parameters. Because the amount of MeHg generated by an ecosystem is influenced by both DOC and sulfate, EPA recommends the FEIS include a comparison of not just the MeHg values, but the MeHg values in relation to existing DOC and sulfate concentrations in the Stibnite area and how those compare to other streams in the national assessment.		
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	31	<p>Major Ions, pH, and Total Dissolved Solids (TDS)</p> <p>In the Surface Water - Major Ions, pH, and TDS section of the DSEIS, EPA recommends the FEIS include in this discussion the levels of sulfate under existing conditions. This information is included in Table 3.9.9, but the significance and trends of this data are not described. Because the levels of sulfate may increase because of mining activity and there are important links between sulfate levels and MeHg production, EPA recommends the FEIS include a description of current sulfate levels. From the table, it appears that most sulfate levels are quite low (<10 mg/L), especially when compared to the national average from the USGS study at 45.9 mg/L.</p>	WTR	<p>A description of the existing sulfate conditions and their implications for water quality has been added to Section 3.9.4.4.</p> <p>Average predicted sulfate concentrations in surface waters are similar to existing conditions with maximum predicted sulfate concentrations rising above those levels but to concentrations less than the 45.9 mg/L value reported for the national average in the USGS study.</p>
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	32	<p>Chemical Release Rates Temperature Correction</p> <p>The DSEIS states “[t]he source terms were then scaled to field conditions to account for differences in reaction rates, temperatures, and liquid-to-solid ratios between laboratory tests and field conditions.”</p> <p>EPA notes that the temperature correction will likely underestimate leaching rates encountered at the mine site. The Arrhenius equation is based on pyrite oxidation and is not specific to other metal/element release rates. Several metals have been shown to have higher release rates at lower temperatures.</p> <p>In addition to the inherent uncertainties in applying the temperature correction factor, an annual air temperature of 2.6°C should not be used for scaling. The annual average incorporates many months of sub-zero temperatures into this average when water is frozen and aqueous geochemical reactions are not occurring. A more conservative annual average would be based only on time periods when the temperature was greater than 0°C. A slightly less conservative approach would be based on an average that substituted 0’s for time periods when the temperature was negative. In addition, temperatures below the surface are often higher than air temperatures, especially when they are insulated with snow cover. Furthermore, chemical reactions are exothermic and can also contribute to increases in subsurface temperatures in geochemically active areas. In addition, under future climatic conditions, the temperature is predicted to increase. Overall, for the FEIS, EPA recommends the chemical release rates not be corrected for temperature during the water quality modeling.</p>	WTR	<p>Humidity cell testing (HCT) is a widely accepted methodology for examining the potential for mined materials to generate acidity and/or leach solutes when exposed to atmospheric conditions. Larger scale field testing would also be informative to this forecasting and is often performed in conjunction with HCTs to assess the differences in sulfide oxidation between field and laboratory conditions. In general, laboratory testing is more aggressive in creating conditions that promote sulfide oxidation, and therefore, provides a conservative quantification of leachate chemistry from mined materials. To translate from laboratory to field conditions, temperature correction factors are commonly applied to reflect the slower sulfide oxidation kinetics at lower temperatures.</p> <p>Model sensitivity associated with the selection of the scaling factor is described in SDEIS Section 4.9.2.4, which notes that the model implications of a larger scaling factor.</p>
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	33	<p>Effects of Deposited Mercury to Watershed</p> <p>The DSEIS indicates actual local mercury deposition rates from project emissions depend on the fractions of particulate versus gaseous mercury emissions. Particulate emissions generally deposit on the ground surface nearer to their source while gaseous emissions tend to deposit farther from the source or potentially become part of global atmospheric mercury burden.</p> <p>We appreciate this information being mentioned in the water quality section of the DSEIS. In the air section of the DSEIS, it suggests that most Hg⁰ will be captured, which suggests that most of the 13.6 lbs/year (6,200 g/year) that is released will be Hg²⁺ and HgP which would deposit locally. However, the results of the AERMOD predictions indicate that a much smaller amount of mercury (0.056 g/year) will be deposited within a square km around the mine site. There seems to be a disconnect between the amount and species of mercury emitted and the amount being deposited to the local watershed. EPA recommends the FEIS assess the potential for enhanced local deposition of Hg²⁺ and HgP of mercury to the local watershed and how this will impact water concentrations.</p>	WTR	<p>The total predicted mercury emission from the Project is 13.6 lbs/year, but the majority of that emission (72%) would be in gaseous form that would enter the global mercury inventory. Deposition modeling predicted the local deposition of the remaining Hg²⁺ and HgP to be 0.056 g/km²/year. This rate would be related to local deposition with the potential to affect site conditions compared to baseline deposition rates (i.e., 12.7 to 13.9 g/km²/year).</p>
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	34	<p>Ratios of Stream Mercury Loads to Atmospheric Mercury Deposition Rates</p> <p>The DSEIS states “[r]atios of stream mercury loads to atmospheric mercury deposition rates have been reported in watersheds affected by gold and silver mining (Domagalski et al. 2016)... Therefore, aerial</p>	WTR	<p>The section has been revised to include the predicted mercury deposition rate from the air quality analysis (i.e., 0.056 g/km²/year compared to a baseline deposition rate of 12.7 to 13.9 g/km²/year).</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Environmental Review Branch)			<p>deposition would have a minor to moderate, long-term effect on particulate mercury loads in streams within the project area watershed.”</p> <p>It is unclear what ratios are being used in the analysis that led to the conclusion of minor to moderate impacts. An earlier version of the DSEIS document stated that “[r]eported ratios of stream mercury loads to atmospheric mercury deposition rates have been reported to be approximately 50-to-1 in watersheds affected by gold and silver mining with a drainage areas less than 500 square kilometers (Domagalski et al. 2016). Application of that ratio to the total mass of mercury emission would suggest that aerial deposition could contribute up to approximately 0.3 pounds per year to streams within the watershed during the operations period, primarily in the form of particulate mercury.”</p> <p>At that time, the EPA commented the ratio of 50 to 1 is not applicable to this situation. Domagalski et al, 2016 is suggesting that the stream Hg loads are 50 times higher than the atmospheric deposition load due to the contribution of non-atmospheric sources in the watershed.</p> <p>Applying the Domagalski ratio of 50 to 1, would indicate that deposition from the mine releases would be 0.006 pounds/ year and then multiplying value by 50 to come up with 0.3 pounds/year. But this large multiplier is a function of untreated mine waste in the watersheds that is overwhelming the atmospheric deposition. This is not applicable to conditions presented in the DSEIS.</p> <p>Our concern is that the DSEIS flips the intention of the 50 to 1 ratio to suggest that only 2% of atmospherically deposited mercury makes its ways into streams. This is inaccurate and opposite of what is presented in Domagalski for gold-silver mine impacted watersheds.</p> <p>While the DSEIS does not make specific reference to the ratio used in the analysis, EPA remains concerned about the basis of the analysis that used the Domagalski ratio of 50 to 1 for these conclusions. EPA recommends the FEIS reassess the ratio used and make corrections accordingly.</p>		The reference to Domagalski has been revised to acknowledge the study but to note that there has been no quantitative application of the ratios reported in that study.
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	35	<p>Ratio to Predict Future MeHg Concentrations</p> <p>The DSEIS states “a ratio method to estimate methylmercury concentrations from predicted total mercury concentrations was applied per the approach and data collection by Holloway et al. (2017) that showed methylmercury concentrations were up to two percent of total mercury concentrations in samples from Sugar Creek and the East Fork SFSR.”</p> <p>EPA recommends the FEIS clarify if the ratio from Holloway is based on dissolved or whole water mercury concentrations and recommends utilizing dissolved concentrations since this is the form that is predicted to be released from the mine operations (i.e., “Predictive modeling indicates that mine facilities and water treatment would contribute dissolved mercury to surface waters primarily during the operating and early post-closure periods”)</p> <p>Also, the Holloway ratio is based on existing conditions between mercury and MeHg and will underpredict ratios that may exist if carbon and/or sulfate levels are increased.</p> <p>Overall, using this ratio to predict future MeHg concentrations likely results in an underprediction of the impacts. For the FEIS, EPA recommends reassessing the use of this ratio and adjusting the assessment accordingly to avoid underpredicting impacts.</p>	WTR	<p>The text has been revised to provide additional details regarding the use of the Holloway et al. (2017) mercury-methylmercury data.</p> <p>Changes in organic content and sulfate concentrations are predicted to be minor compared to existing conditions. Therefore, utilizing the maximum observed mercury methylation rate for the site provides a reasonable estimate for potential future mercury methylation on site.</p>
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	36	<p>Model Sensitivity and Uncertainty Air Temperature Correction Factors</p> <p>The DSEIS states “[a]ir temperature correction factors used to scale laboratory reaction rates to field conditions by the model could underestimate actual reaction rates and chemical releases from mined materials, and hence, surface water quality impacts.”</p> <p>We appreciate that the potential for underestimating reactions rates due to the temperature correction factor is mentioned in the DSEIS. However, for the FEIS, EPA suggests that the model be run without the temperature correction factor applied to the chemical source terms in order to provide an upper bound of leaching potential. In general, EPA suggests a preference to overpredict environmental impacts with a caveat that the predictions may be conservative rather than the other way around.</p>	WTR	Humidity cell testing (HCT) is a widely accepted methodology for examining the potential for mined materials to generate acidity and/or leach solutes when exposed to atmospheric conditions. Larger scale field testing would also be informative to this forecasting and is often performed in conjunction with HCTs to assess the differences in sulfide oxidation between field and laboratory conditions. In general, laboratory testing is more aggressive in creating conditions that promote sulfide oxidation, and therefore, provides a conservative quantification of leachate chemistry from mined materials. To translate from laboratory to field conditions, temperature correction factors are commonly applied to reflect the slower sulfide oxidation kinetics at lower ambient temperatures.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>Later the DSEIS mentions “[t]he model is most sensitive to ...increasing the reaction temperature” and “increasing the reaction temperature in mined materials and pit walls was shown to produce higher post-closure arsenic concentrations in the pit lakes and downstream assessment nodes.”</p> <p>Presumably, “increasing the reaction temperature” refers to using the humidity cell test (HCT) results that were obtained from the lab (at 25°C) without decreasing the reaction temperature to reflect the annual average measured at the mine site (2.6 °C). EPA recommends the FEIS provide details clarifying if they were still decreased from the lab, but less than had been done originally. It should also be taken into consideration that under future climate conditions, the annual average air temperature at the mine may increase, which would result in an underpredictions of chemical releases rates if the current rates are based on the average of historical temperature.</p> <p>Presumably these results represent uncorrected laboratory-based source terms, as opposed to a dataset where the reaction temperature has been increased beyond what was measured in the lab. Given that the temperature correction factor was a significant variable impacting the water quality predictions (i.e. correcting the chemical release rates measured at 25 °C down to 2.6 °C), this underscores our comments for the FEIS to include the uncorrected rates in the model predictions unless specific evidence can be provided to support the use of the temperature corrections.</p>		Model sensitivity associated with the selection of the scaling factor is described in SDEIS Section 4.9.2.4, which notes the model implications of a larger scaling factor.
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	37	<p>Atmospheric Mercury Deposition</p> <p>The DSEIS states “[t]he surface water quality model predictions do not include mass loading inputs from permitted IPDES outfalls that would be required for the SGP. Additionally, mercury inputs from atmospheric deposition caused by the SGP have not been considered in the model. These additional loads were discussed qualitatively or semi-quantitatively in the analysis above but could modify future analyte concentrations compared to predicted values.”</p> <p>As mentioned above, we appreciate disclosing this information in the DSEIS; however, for the FEIS, EPA recommends accounting for atmospheric deposition in the water quality predictions to provide a holistic assessment of water quality impacts.</p>	WTR	The section has been revised to include the predicted mercury deposition rate from the air quality analysis (i.e., 0.056 g/km2/year compared to a baseline deposition rate of 12.7 to 13.9 g/km2/year).
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	38	<p>Site-wide Water Chemistry (SWWC) Model-predicted Concentrations</p> <p>The DSEIS states “[m]odel-predicted concentrations generated by the SWWC Model are for the dissolved fraction only and may underpredict concentration levels for constituents such as mercury that have been shown to occur in particulate form.”</p> <p>As mentioned previously, we appreciate disclosing this information in the DSEIS; however, for the FEIS, EPA recommends a preference to account for whole water concentrations (which is reflective of the 12 ng/L chronic criteria value for mercury).</p> <p>There are multiple aspects of the analysis in the DSEIS where the estimated impacts represent underpredictions. While each individual aspect may represent a relatively minor underpredictions, collectively they could add up to the impacts to air and water being significantly higher than what is anticipated in the DSEIS. As noted in the comments above, we recommend that underpredictions be remedied to develop conservative predictions of water quality impacts. This is important in order to disclose impacts more accurately and also to ensure that water management, control, and treatment plans will be effective at protecting water quality.</p>	WTR	The section has been revised to relate the magnitude of predicted particulate mercury deposition from the air quality analysis (i.e., 0.056 g/km2/year compared to a baseline deposition rate of 12.7 to 13.9 g/km2/year).
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	39	<p>Mitigation Measures for Mercury</p> <p>Mercury concentrations in West End Creek will increase from the baseline of approximately 4 ng/l to approximately 53 ng/l during mining operations (for 10 years). This represents an increase in mercury loading and likely impairment to West End Creek, which is fully supporting its beneficial uses and is a high-quality water under Idaho’s antidegradation policy. Additionally, it will also increase loading downstream to Sugar Creek, which is already listed as impaired under Clean Water Act Section 303(d) for mercury. The increase is due to the diversion of West End Creek, which is a result of the proposed SGP. Even though West End Creek is elevated in mercury above the proposed West End pit, by</p>	WTR	The predicted changes in mercury concentrations in West End Creek relate to the diversion of existing surface water flow containing mercury around the mining area. There is no mercury being added to the system, but an existing mercury load would be detectable further downstream because of the diversion. The net effect of that mercury on downstream surface waters would be the same as the existing condition. The Surface Water Chemistry subsection of SDEIS Section 4.9.2.2 describes the effects of the West End Creek diversion.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			diverting the Creek and mining the pit, the SGP is resulting in an increase in the amount of mercury into lower West End Creek and Sugar Creek from current conditions. For the FEIS, EPA recommends that a mitigation measure be developed to avoid the predicted mercury water quality standard exceedances during operations or offset the additional amount of mercury being added to the system (e.g., by removing other mercury sources) to avoid further water quality degradation. Because mercury is bioaccumulative, effects to the system will likely extend beyond the lifespan of the SGP.		
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	70	<p>Table 2.8-1 Alternative Comparison and Impact Summary (for 2021 MMP)</p> <ul style="list-style-type: none"> The DSEIS indicates low flow will be reduced at some locations during some periods of the SGP operations. EPA recommends the FEIS add a sentence to the table describing how far downstream (in feet or miles) from the SGP low flow conditions would occur so that the geographic extent of low flow impacts to the EFSFSR are clearly disclosed. Note that this comment also applies to the same sentence on page ES-14. In the summary table 2.8-1 2021 MMP, the TSF area groundwater summary provides the estimated changes in groundwater concentrations. EPA recommends the FEIS describe how far from each facility the groundwater concentrations would remain elevated above the baseline so that the geographic extent of groundwater contamination caused by the SGP is disclosed. The DSEIS states, “[f]or mercury, while the predicted concentrations do not exceed the aquatic life criterion based on water column, it is uncertain whether incremental change in water column concentrations beyond baseline would cause fish tissue concentrations to exceed the tissue-based criterion.” EPA recommends the FEIS add this sentence to the summary table 2.8-1 2021 MMP, for surface water quality since it relates to uncertainties associated with achieving Idaho’s fish tissue-based mercury water quality criterion for human health. According to pg. 4-308, “[f]unctional loss due to other indirect effects, including changes in hydrology, water quality, and increase dust and/or mercury deposition has been examined through inspection of dewatering drawdown and distance to roadways, but is difficult to quantify precisely. As a result, functional units that would be lost if these indirect effects occur, may be underestimated.” EPA recommends adding this statement or something similar to the summary table 2.8-1 2021 MMP, Wetlands for the FEIS. Otherwise, the exact acres of wetlands lost or changed provided in the table imply a level of certainty that does not exist since indirect (secondary) impacts are underestimated and not quantified. In addition, we recommend that a similar uncertainty statement be added to the Executive Summary on page ES-17. 	WTR	<p>Table 2.8-1 has been modified per the comment.</p> <p>Changes in surface water flows are expected to be within measurement error following the confluence with Johnson Creek.</p> <p>The magnitude of potential increases in groundwater chemistry are based on the predictions for seepage from the TSF embankment and buttress (SDEIS Table 4.9-8) and from the development rock backfills in the Midnight, Hangar Flats, and Yellow Pine pits (SDEIS Tables 4.9-13,4.9-14, and 4.9-15).</p> <p>SDEIS Figure 4.9-20 illustrates the starting locations for groundwater affected by pit backfill or the West End Pit lake and the destination for that groundwater. The areal zone between the starting locations and the destinations represents the area where groundwater concentrations could be increased relative to existing conditions by the Project.</p> <p>The uncertainty regarding fish tissue concentrations has been captured in the Fish Resources and Fish Habitat section of Table 2.8-1, i.e., "The effects of incremental change in water column mercury concentrations on fish tissue concentrations is uncertain."</p> <p>The clarification regarding indirect effects on wetlands has been added.</p>
Chu, Rebecca (Chief, Policy and Environmental Review Branch)	18834	72	<p>Surface Water and Groundwater Water Quality</p> <ul style="list-style-type: none"> The SDEIS states that for copper and mercury, impacts may be minimal but uncertainties in predicting future conditions exist. EPA recommends the FEIS describe the mitigation and monitoring that will occur to reduce the uncertainties and actions that would be taken if impacts are more than minimal and result in exceedances of Idaho’s CWA aquatic life criteria for copper and mercury. For the FEIS, EPA recommends noting in a footnote of the Table 3.9-6a Average MWMP Results – Development Rock and Ore and in the text that refers to the Table 87 that the detection limit used for this test for mercury (100-200 ng/L) is significantly above the CWA aquatic life criterion of 12 ng/L. Therefore, while some concentrations were above 200 ng/L, when values were less than this it does not indicate that the leachate would meet criteria. The same comment also applies to cadmium, copper, selenium, silver, thallium and lead. If similar issues also exist in other Tables in the text, EPA recommends adding a similar note indicating where the detection limit of the analysis is above the regulatory criteria level. The DSEIS indicates, under existing conditions, streams in the SGP area (except for West End Creek) are listed as impaired in accordance with CWA Section 303(d). The causes for listing of these waters are associated with arsenic (plus antimony and mercury at some locations) for exceedances of Idaho's water quality standards (WQS). Operational and post-closure concentrations of these elements in the East Fork 	WTR	<p>Water quality monitoring would be required under an approved Water Resources Monitoring Plan.</p> <p>The footnote regarding analytical detection limits for mercury has been added to Table 3.9-6a.</p> <p>The Executive Summary provides an appropriate summary for the water quality analysis. Readers interested in the detail can access the additional information in the water quality section and supporting documents. The standards for total and dissolved mercury have been added to the header of Table 3.9-10b.</p> <p>A discussion of cyanide concentrations in the vicinity of the TSF has been added to the EIS.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>SFSR are predicted to be comparable to or less than the existing conditions.⁸⁸ EPA recommends the FEIS add a sentence to this statement in the Executive Summary that identifies that under the proposed action West End Creek is predicted to exceed Idaho's CWA mercury aquatic life criterion for approximately 10 years during operation. The predicted mercury Idaho CWA WQS exceedances are described in the main text of the SDEIS, but we recommend that they also be identified in the Executive Summary.</p> <ul style="list-style-type: none"> • For Table 3.9-10b, EPA recommends the FEIS add Idaho's CWA mercury criteria to the table header row as is done for the other constituents. • Since cyanide is predicted to be elevated in the tailings pond, EPA recommends the FEIS include cyanide in Table 4.9.6. Predicted TSF Surface Water Chemistry so that predicted cyanide concentrations are disclosed. • EPA recommends the FEIS add cyanide to Table 4.9-8 Predicted Groundwater Chemistry Underlying the TSF for the same reason as above. 		
Shawn Phillips	18836	3	<p>And those impacts will continue to be felt downstream, threatening increasingly commercial waters ... yet Perpetua Resources only considers environmental impact in a discrete chunk around the footprint of their mine.</p> <p>Again you are better equipped to understand real-world results, and I'm sure you also understand that small percentage changes can send ecosystems past tipping points, which push recreation and commercial operations past tipping points.</p> <p>But if Perpetua doesn't know how river systems distribute chemicals, they don't have any business running a mine in a vibrant and valuable river system ... and if they do understand but ignore, they're equally disqualified.</p>	WTR	SDEIS Section 4.9.2.2 describes the water quality effects of the Project. Water quality effects extending to wilderness areas downstream of the Project area are not anticipated.
Small, Nathan (Chairman, Fort Hall Business Council, Shoshone-Bannock Tribes)	18903	12	<p>The SEIS and supporting appendices rely heavily on 'Best Management Practices' to ensure that the projected loading of the East Fork South Fork Salmon River is within the legal threshold put forth by the Idaho Department of Environmental Quality. While this Project does note increases for mundane contaminants (sediment and/or temperature) that will have long-term effects on the environment, the Tribes still have concerns with loading particular contaminants on human health for our members utilizing resources from the area. The Project plans to implement a great deal of restoration actions in the initial phase and then completing the remaining restoration actions post-mining, with a timeline showing 50-100 years post-mining things will return to 'normal'. While it is understood that the best efforts to reduce constituents of concern will be taken at the outset of restoration design, inadvertent releases or severe weather can occur suddenly at this elevation (with potentially serious consequences) and the 50-100+ year timeline only increases the risk threshold for those stochastic events to compromise elements of restoration in the Project plan.</p>	WTR	<p>SDEIS Chapter 2 describes Project EDFs and Forest Service requirements that minimize the risk of inadvertent releases and severe weather along with response to these events.</p> <p>SDEIS Section 4.9.2.4 describes the uncertainties in forecasting water quality effects of the Project while SDEIS Section 4.9.3 describes mitigation measures to reduce those uncertainties.</p>
Small, Nathan (Chairman, Fort Hall Business Council, Shoshone-Bannock Tribes)	18903	13	<p>Increased exposure of legacy leachates in tailings have relatively unknown concentrations of multiple constituents of concern, including legacy cyanide and arsenic, that have the potential to be mobilized during extraction/restoration activities. There is a possibility that the specific monitoring locations will not adequately pick up problems, and correlate those problems with specific locations within the mine site, in a timely fashion; increasing the likelihood that issues will be compounded by duration of exposure and/or ability to remedy releases. The Tribes' perspective is that intensive monitoring protocols should be required throughout all mining phases, with rigorous post-mining monitoring required throughout the projected life of reclaimed features (pits, tailings piles, ore stockpiles, etc.). As is often the case in new mining proposals, the water quality program relies heavily on adaptive management processes that do not necessarily include the collection of current data to inform management decisions based on established action triggers/metrics. This is particularly relevant to this proposal as most of the monitoring protocols rely on spot checks once every three months, instead of active/continuous monitoring during ground disturbance and post-closure.</p>	WTR	<p>The Project would include surface water and groundwater monitoring in the construction, operations, closure, and post-closure periods. As described in Section 4.9.3, the monitoring program would be adaptable and would be adapted per the monitoring results observed. The IDEQ permits related to surface water and groundwater impacts would also incorporate monitoring and reporting requirements that were not yet established when the SDEIS was prepared.</p> <p>An associated mitigation measure has been added to Section 4.9.3 of the Final EIS.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Small, Nathan (Chairman, Fort Hall Business Council, Shoshone-Bannock Tribes)	18903	14	The SEIS describes a discharge of sewage and waste into the watershed that is anywhere from 25,000 - 50,000 gallons per day of sewage discharge from the treatment plant. The Project doesn't describe any detailed information about the design of this sewage treatment plant or what the potential effluent is going to be. The Tribes are very concerned about this aspect because our Reservation is immediately downstream of a sewage treatment plant that releases serious contaminants. So why is the Forest Service allowing this mining operation to contaminate the pristine waters downstream, where our members are in those waters, without actually evaluating what that facility will look like and disclosing it to the public? The purpose of the SEIS is to describe every component of the Project, and this is one example where the questions cannot be answered by the information presented in the document.	WTR	Proposed sewage treatment is described in SDEIS Section 4.9.2.2 along with its potential effects on downstream water chemistry. Any discharge of wastewater to receiving streams would be regulated by permits issued by the IDEQ. These permits would be specifically designed to protect downstream beneficial uses of the surface waters. Detailed designs for the wastewater treatment systems are not necessary for this NEPA analysis because the proposed water treatment technologies are typical and well-proven but would likely be required for the IDEQ permits.
Small, Nathan (Chairman, Fort Hall Business Council, Shoshone-Bannock Tribes)	18903	15	The Tribes remain adamantly opposed to any course of action that would contribute to the existing levels of contamination from legacy mining or increase the risk of mobilizing contaminants during mining activities. This concern is compounded by the legacy risk this action will leave in the South Fork Watershed (50-100+years) when considering the known effects of climate change that will change the seasonal thermal regime, hydrologic cycle in the basin, and, the potential for large scale wildfire and/or flooding events. With water resources being one of our most sacred and base elements of all life, the risk to the watershed from mineral extraction is one of our foremost concerns; unfortunately, the Project does not adequately address these impacts or recommend suitable mitigation measures to ensure water quality does not deteriorate.	WTR	The predicted effects of the Project on water chemistry are described in SDEIS Section 4.9.2.2 along with a description of forecast uncertainties in Section 4.9.2.4. The Project is not predicted to modify water chemistry compared to the existing condition and mitigation measures designed to address forecasting uncertainties are described in Section 4.9.3.
Small, Nathan (Chairman, Fort Hall Business Council, Shoshone-Bannock Tribes)	18903	20	During initial project exposure to the public and in the initial DEIS for the Project, the proponents and Forest Service were quick to point to 'state of the art' water quality treatment for the mine. Based on new assumptions, generally presented as new 'liners and caps', will eliminate the need for water treatment after 40 years; because if there is a problem at year 39 it will definitely be resolved perpetually following year 40. An arbitrary deadline for maintenance of water quality treatment facilities only serves to benefit the proponent of the operations; obviously it is in the public interest to require water treatment for as long as necessary to meet established standards for human consumption, human health, and aquatic life. The Tribes unequivocally oppose allowing an arbitrary 40-year timeline to dictate the extent of water quality treatment; if this mining operation causes impacts to water quality in perpetuity then they need to commit to treat that water impacted for just as long.	WTR	SDEIS Section 4.9.2.2 describes how water treatment would be utilized to manage water quality effects from Project facilities. The 40-year time period is approximate and provides the estimate for the duration of that water treatment activity, but cessation of water treatment would depend on monitoring observation of site conditions that could result in a shorter or longer water treatment duration depending on those monitoring results.
Small, Nathan (Chairman, Fort Hall Business Council, Shoshone-Bannock Tribes)	18903	27	Thank you for reducing temperature and arsenic impacts to the EFSFSR by modifications to your mine plan. However, temperature loads are still unacceptable, as submitted in the SDEIS. Please continue to seek further reductions in these impacts as well as others such as mercury, lead, and cyanide.	WTR	Predicted surface water concentrations in the East Fork SFSR are currently near or below existing conditions. Measures to mitigate stream temperatures are described in SDEIS Section 4.9.3.
Small, Nathan (Chairman, Fort Hall Business Council, Shoshone-Bannock Tribes)	18903	28	Septic drain fields should be located according to Idaho DEQ requirements. All potable wells and potable water supply for workers should be permitted as Public Water Systems under the Idaho DEQ.	WTR	Sewage generated by Project employees would be managed via a water treatment plant rather than a septic drain field. The Project includes a public water system to supply potable water for employees.
Small, Nathan (Chairman, Fort Hall Business Council, Shoshone-Bannock Tribes)	18903	32	Please ensure and verify that development rock used for roads, parking areas, or concrete aggregate are suitable, not leachable, and does not contain radon-reducing constituents.	WTR	The geochemical suitability of proposed road materials was assessed with the study (SRK 2020) utilized and cited in the water quality analysis presented in SDEIS Section 4.9.2.2.
Small, Nathan (Chairman, Fort Hall Business Council,	18903	33	When discussing "liners", "lining", and other containment components, please be specific each time the term is used. Just saying "lining" or "liner" tells the reader nothing and does not inspire confidence that appropriate materials will be used to prevent contaminant migration.	WTR	The EIS text has been revised to indicate that liners and lining refer to the use of geosynthetic plastic liners.

Shoshone-Bannock Tribes)					
Small, Nathan (Chairman, Fort Hall Business Council, Shoshone-Bannock Tribes)	18903	41	The construction and operation of mine infrastructure may impact water quality and quantity within the analysis areas. The Tribes request that the following products and physical parameters be included in all environmental monitoring of mine and operation areas. Indicators: <ul style="list-style-type: none"> • Mineralized waste generated (tons, closure stabilization, and water chemistry). • Exposures of ore bodies/potentially acid-generating material (rock and water chemistry). • Legacy mine tailings and waste rock (rock and water chemistry). • Methylation rates for mercury (water chemistry). • Surface water quality (water chemistry and temperature). • Groundwater quality (water chemistry). • Stream flow characteristics (daily, seasonal, annual). • The extent, magnitude, and duration of changes in groundwater levels (feet of drawdown). 	WTR	The requested information appears in the Water Quantity Specialist Report and the Water Quality Specialist Report. These reports are cited and summarized in SDEIS Sections 4.8 and 4.9, respectively. They were also made available in their entirety at the same time as the SDEIS was released. Monitoring will be addressed in project monitoring plans.
Small, Nathan (Chairman, Fort Hall Business Council, Shoshone-Bannock Tribes)	18903	43	Yellow Pine Pit Lake is NOT "small" (222 acres and 720' deep). 2.4.5.1 Please remove the word "small".	WTR	Section 2.4.5.1 has been revised to remove the word "small." Water depth is currently in the 135' range.
Small, Nathan (Chairman, Fort Hall Business Council, Shoshone-Bannock Tribes)	18903	44	Please detail the water rights issue for use of groundwater seepage and in-pit surface water runoff in the ore processing plant, including 2.4.5.1 documentation of water rights.	WTR	SDEIS Sections 3.8.4.2 and 3.8.4.3 describe the status of water rights in the Project vicinity. Effects of the Project on water rights are described in SDEIS Section 4.8.2.2. As described in SDEIS Section 3.8.3, the issuance of water rights for the Project allowing diversion of groundwater, surface water, and/or mine contact water for use in ore processing is the purview of the IDWR with its decision made in a separate Idaho State permitting process and action.
Small, Nathan (Chairman, Fort Hall Business Council, Shoshone-Bannock Tribes)	18903	45	During the use of lower grade ore (either expected or unexpected) and as metals prices fluctuate, this reviewer has concerns that the mine lifetime, thus the remediation work after mining, will be extended/delayed into the future, further causing devastating impacts to the EFSFSR and surrounding environment. And would low metals prices be used as an excuse to not move low-grade ore from the tailings piles or the ore stockpiles?	WTR	Changes in metal prices and/or variations from expected ore grades have the potential to affect the timing of Project closure and reclamation. Low metal prices could also result in low-grade ore stockpiles being closed and reclaimed per the Reclamation Closure Plan rather than processed. The proposed ore stockpiles are located on top of the TSF Buttress. The proposed closure of the TSF Buttress by installation of a geosynthetic liner covered with growth media and revegetated would inhibit leaching of any remaining stockpile material.
Small, Nathan (Chairman, Fort Hall Business Council, Shoshone-Bannock Tribes)	18903	46	Define and reference the physical and chemical stability determinations of development rock. Who will monitor this? Who are data reported to? And, who makes the suitability determinations? Agencies?	WTR	Monitoring of development rock would be performed by the Project operator and consist of mined tonnages and placement in approved storage facilities plus laboratory testing for acid-generation potential and metal leaching potential. Monitoring results would be reported to the Forest Service and other Idaho state regulatory agencies that would assess whether development rock management meets requirements for physical and chemical stability.
Small, Nathan (Chairman, Fort Hall Business Council, Shoshone-Bannock Tribes)	18903	57	7.2.2.2 2021 MMP Traffic by heavy construction vehicles and equipment would occur throughout the road and SGP construction periods. The Motorized Mixed-Use Analysis Report (DJ&A, PC 2017) anticipates an addition of 65 vehicles per day on the Burnt Log Route during construction, with 69 percent of those anticipated to be heavy vehicles. As there are currently no buildings or operations in the Burnt Log Creek watershed, the addition of the Burnt Log Maintenance Facility would likely have an incremental increased effect on stormwater runoff, potential leaks or spills of automotive fluids, and sedimentation of dust from on-site road sanding material storage and vehicle travel over gravel surfaces. However, the facility would change less than 0.1 percent of the watershed to industrial use from forestry use, so any effects on water quality, ORVs, or the Wild classification of Burnt Log Creek are likely to be negligible.	WTR	The rationale for describing the level of consequence associated with the Burntlog Route activity is discussed in SDEIS Section 4.9.2.2. The nature of the activities, the area within the watershed where activity would occur plus Project designs and requirements to minimize effects are expected to result in changes in conditions that would be too small to be physically measured by normal methods or would be imperceptible (as described in SDEIS Table 4.1-1). As such, water quality effects associated with the use of the Burntlog Route on Tribal Treaty Rights are not anticipated. Mitigation measures for Burntlog Route use on Tribal Treaty Rights are described in the EIS under the Tribal Rights and Interests section.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			The Tribes disagree. The effects on water quality, ORVs, Wild classification and cultural and customary access through Treaty protected rights will be significant and must be classified in this manner. Runoff in the creek is expected, potential leaks and spills from large heavy equipment is expected and dust, debris is not just incremental but significant. The true impacts from this construction must be documented in a realistic manner and communicated to the public that way. How will the loss of Treaty protected rights for the Shoshone-Bannock Tribes be mitigated? How do these activities com It with Environmental Justice?		
Jolie Drake	18929	3	As the second longest free-flowing river in the lower 48, the South Fork of the Salmon River (SFSW) provides habitat for species protected under the Endangered Species Act. But mining efforts are responsible for the SFSR's shocking rank of #5 on America's Most Endangered Rivers 2020 Report. Home to native westslope cutthroat trout, and critical habitat and active spawning grounds for threatened steelhead and endangered Chinook salmon and bull trout, this river is the foundation of ongoing efforts to restore these species. Past decades of heavy mining in the Stibnite area have already proven detrimental to water quality, landscapes, natural habitats, wildlife, and fisheries. In an effort to curb arsenic and mercury leaking into the river, miners unsuccessfully tried to reroute the headwaters by building a dam, but it blew out in 1965. Proposed as a Superfund site, U.S. taxpayers have already invested over four million dollars cleaning up damage from previous Stibnite mining operations. Yet, despite decades of restoration efforts, material contaminants remain in mine tailings, soil, groundwater, sediment and surface water. According to the U.S. Geological Survey's Idaho Water Science Center, the average concentration of dissolved arsenic currently in the EFSF is 57 micrograms per liter - five times the human health benchmark, and with highest reading dangerously close to the aquatic life long-term toxicity value of 150 micrograms. As an example of the damage mining can do to the environment, Panther creek, a nearby tributary to the Salmon River, suffered from mining operations at Blackbird Mine, releasing copper, arsenic, and cobalt into its tributaries. Before the mine, Panther Creek, like Stibnite, supported abundant Chinook and steelhead populations. But from the 1960's to the 1980's, no fish and few aquatic invertebrates could be found within 25 miles of the mine. In an effort to revitalize the fish population, years of studies transplanted fish, but fish populations failed to recover, and tests showed close to a 100% mortality rate. The watershed had barely any disturbances other than water quality, proving that mining-related pollution was the reason for these lethal effects.	WTR	No further response required. General in nature or position statement. It is acknowledged and understood that concerns regarding potential long-term environmental impacts, ecological integrity, and the well-being of potentially affected communities are valid and important to consider. During the decision-making process, the Forest Service will seek to identify the best possible balance between environmental protection, community needs, and sustainable forest management. Note that SDEIS Section 1.3 describes the CERCLA history of the Stibnite site.
Leah K. Corrigan	19000	5	The DEIS fails to provide an adequate analysis of the impacts on surface water and groundwater quantity and quality. All of the alternatives except for the no action alternative are likely to have significant negative impacts on the quantity of surface water and ground water in all drainages within the analysis area. In addition, all of the alternatives except for the no action alternative are likely to have significant negative impacts on water quality. Water quality will be negatively impacted by acid rock drainage and/or metals leaching from mineralized rock in the mine pits, development rock storage facilities (DRSFs) and the tailings storage facility (TSF). In addition, the project will negatively impact water quality through causing increased mercury methylation in adjacent waterbodies through emissions and other activities. Arsenic, antimony, mercury and other metals will contaminate surface and ground water for many years. I am very concerned about the impacts of the project on surface water and groundwater quantity and quality. Negative impacts on water quantity and quantity can have far reaching ramifications for the health of the Salmon River ecosystem as a whole, and many other things that I value that depend on a healthy river ecosystem, including fish populations, wildlife, recreation opportunities, human health, and businesses and local economies. For these reasons, it is critical for the DEIS to provide an adequate analysis of the impacts of the alternatives on water quantity and quality. There are substantial uncertainties in the model used to predict water quantity and quality impacts in the DEIS. As a result, the model likely underestimates negative impacts that will result from the four action alternatives.	WTR	SDEIS Sections 4.8 and 4.9 describe the predicted effect of the Project on water quantity and water quality, the uncertainties associated with model predictions, and monitoring and mitigation measures developed to address modeling uncertainties. Predicted Project effects on arsenic, antimony, mercury, and other metal concentrations along with mercury methylation are included in SDEIS Section 4.9.2.2. The Project has a neutral to beneficial effect on these concentrations due to removal of legacy mined materials present in the surface water drainages. Test work performed on materials that would be mined by the Project indicate that acid rock drainage is not anticipated. However, metal leaching is a likely effect that is addressed through the use of liners, geosynthetic covers, and water treatment. Site hydraulic data do not indicate higher levels of transmissivity along fault zones, observing low bedrock transmissivity in the vicinity of faults and shear zones. SDEIS Section 4.8.2.4 describes the level of uncertainty associated with use of groundwater flow models and Section 4.8.3 includes monitoring and mitigation measures designed to reduce the effects of model uncertainties.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>The DEIS acknowledges that there are several sources of predictive uncertainty for the hydrological model, including the following:</p> <ul style="list-style-type: none"> - A limited number of hydraulically tested wells and boreholes; - Typical limitations of data derived from hydraulic tests; - Uncertainty as to if any of the fault zones near the proposed pits were hydraulically tested - Not evaluating model predictive sensitivity to various possible degrees of hydraulic transmissivity of the fault zones, which have not been represented in the model; - Lack of a long-term bedrock aquifer test. Future documents will be updated with the results of the 2019 test when available. <p>The fact that the model does not evaluate model predictive sensitivity to various possible degrees of hydraulic transmissivity of the fault zones, is of particular concern. The DEIS acknowledges that the analysis area is cut by several major fault zones, and that the bedrock within the analysis area is faulted and fractured. The DEIS also acknowledges that faults can serve as conduits for groundwater flow. If the faults do serve as conduits to groundwater flow, they could increase hydraulic connectivity, and result in significantly different predictions with respect to the impacts of the project on surface and ground water quantity and quality.</p>		
Leah K. Corrigan	19000	6	<p>The DEIS indicates that there will be major impacts on the quantity and quality of surface and ground water resources. In turn these changes to water quantity and quality will have significant, long-term negative impacts on streams and rivers that support endangered fish, as well as other fish populations that are highly valued by the public for the angling and other recreational opportunities they provide. Given the sensitive location of the project and the long-term nature of the potential impacts, it is imperative to carefully examine “reasonably foreseeable” future outcomes of mine development, as required by NEPA. This includes ensuring that major uncertainties in the model, do not result in a failure to carefully examine all reasonably foreseeable impacts on water quantity and quality.</p> <p>The DEIS makes an unsupported argument that, because the modeling approach and data used by Brown and Caldwell are within the typical scope of modeling data for similar projects, the model is adequate. However, it is not clear that these “typical” projects have the same potential for massive adverse environmental impacts that this proposed project does, due to its location at the headwaters of the ESFSR, and the resources at stake downstream.</p> <p>The DEIS goes on to make an unsupported statement that development of alternative conceptual and numerical models to explore the influence of faults and fractures in the analysis area would not be realistic. However, the DEIS provides no information to support this statement. The DEIS provides no estimate of how much it would cost to develop alternative conceptual and numerical models, what type of expertise or data would be required, or how much time it would take. In addition, hydrologic models that explicitly model flow through faults and fracture zones or evaluate model predictive sensitivity to various possible degrees of hydraulic transmissivity of the fault zones, are considered to be important to development of accurate hydrologic models of the impacts of mineral extraction. In addition, hydrologic models that use these or other approaches to exploring the influence of faults, are common. For example, see the following:</p> <ul style="list-style-type: none"> - https://www.environment.gov.au/system/files/resources/877d5b40-4269-4708-a55f-b5e25df21b4b/files/simulating-the-groundwater-flow-dynamics-of-fault-zones.pdf - https://agupubs.onlinelibrary.wiley.com/doi/abs/10.1029/95WR01178 - https://www.pebbleprojecteis.com/files/2c8a62a6-dedc-4981-88aa-377276c09c34 - https://agupubs.onlinelibrary.wiley.com/doi/abs/10.1029/95WR01178 - https://www.usbr.gov/uc/envdocs/eis/Paradox/20191200-PVU_DEIS_Vol3_Apps_E-J_508.pdf 	WTR	<p>The EIS relies on government-supported numerical models that are commonly applied to analyses of water quantity and water quality effects of mining projects. These model applications are consistent with other Forest Service mining EIS’s and are recommended for use by other regulatory agencies such as the BLM and the Nevada Division of Environmental Protection.</p> <p>Site hydraulic data do not indicate higher levels of transmissivity along fault zones, observing low bedrock transmissivity in the vicinity of faults and shear zones.</p> <p>SDEIS Section 4.8.2.4 describes the level of uncertainty associated with use of groundwater flow models and Section 4.8.3 includes monitoring and mitigation measures designed to reduce the effects of model uncertainties.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>- https://www.mdpi.com/2075-163X/10/8/727/htm</p> <p>The DEIS also states that such a model would be unlikely to produce significantly different predictive results. However, the DEIS also provides limited information to support this statement. As acknowledged in the DEIS, faults can act as conduits to groundwater flow. In addition to influencing impacts on surface and ground water, faults can provide conduits for the escape of mine influenced water from the mine site. At other mine sites, flow along faults has been demonstrated to be a key factor in preventing the containment of mine-influenced waters (https://www.mdpi.com/2075-163X/10/8/727/htm). The DEIS fails to disclose the potentially significant impacts that could occur if faults provide conduits for ground water flow or if flow along faults prevents containment of mine influenced waters.</p>		
Leah K. Corrigan	19000	7	<p>The FS acknowledges that existing data from long-term pumping bedrock aquifer testing would improve characterization of hydraulic properties of the bedrock formations. This would help to ensure that major uncertainties in the model, do not result in a failure to carefully examine all reasonably foreseeable impacts on water quantity and quality. The model should be updated based on this data, and the FS should prepare a new or supplemental EIS that discloses how inclusion of this data changes model predictions with respect to impacts on water quality and quantity.</p> <p>Another major flaw of both the hydrologic model and the analysis of the impacts of the action alternatives on surface water quality, is the failure to consider the potential for floods to cause increased erosion and overflow and breach of tailings ponds. The DEIS does not disclose that the streams in the analysis area experience regular peak floods and larger floods at predictable time intervals, including 100 year peak floods. In addition, the hydrologic model and analysis of impacts fail to provide any predictions regarding how such floods moving through the analysis area, could affect water quality in the analysis area and downstream. The U.S. Geological survey provides high quality data on mean annual floods likely in the analysis area, as well as peak floods at a range of time intervals, including 100-year peak floods, that are available to inform analysis of how floods might impact water quality (https://streamstats.usgs.gov/ss/, https://streamstatsags.cr.usgs.gov/gagepages/html/13311000.htm). A 100-year peak flood is reasonably likely to occur within the time period when such a flood could move through areas disturbed by mining, tailings ponds and other areas impacted by mining, and cause increased movement of contaminants from the project area into streams and watersheds downstream.</p> <p>Further, given that the FS relies almost entirely on the model predictions in analyzing the impacts of the alternatives on water quality and quantity, it is critical to audit the model. Mistakes made in inputting model inputs, running verification simulations etc. could result in substantial changes in the outcome of model predictions. The Forest Service should audit the model, and include the results of the audit in a new or supplemental DEIS.</p>	WTR	<p>The Final EIS describes the new bedrock pumping test data available since publication of the SDEIS and its relationship to the characterization of hydraulic properties and water management forecasts.</p> <p>Flood events were incorporated into the design of the TSF facility, stormwater diversions, and surface water controls (see SDEIS Tables 3.8-3 and 3.8-4).</p> <p>The Final EIS describes the results of the numerical model audit commissioned by the Forest Service.</p>
Leah K. Corrigan	19000	8	<p>Climate change and wildfire may exacerbate negative impacts of the action alternatives on surface and groundwater quantity and quality, especially over the long-term. Climate change may reduce precipitation and snowpack and increase wildfire frequency and intensity. All of these factors could result in cumulative impacts on water quantity and quality not adequately analyzed in the hydrologic model or the DEIS. The hydrologic model does not model the potential additive impacts of climate change and wildfire on surface and ground water quantity and quality.</p>	WTR	<p>On January 9, 2023, the Council on Environmental Quality (CEQ) published interim “National Environmental Policy Act Guidance on Consideration of Greenhouse Gas Emissions and Climate Change” in the Federal Register (CEQ 2023). CEQ grants agencies the discretion to decide whether to apply the guidance to NEPA analyses that were in progress when the guidance was issued. The interim CEQ guidance was published late in the development process for the SGP DSEIS, and therefore this EIS will primarily rely on earlier CEQ guidance on considering climate change in NEPA (CEQ 2016). For example, this EIS does not include all new recommendations such as applying social cost of GHG estimates to the incremental metric tons of each individual type of GHG emissions expected from the Proposed Action and its alternatives. However, this EIS does analyze the two fundamental considerations required by current and former iterations of CEQ climate change guidance: (1) the potential effects of a proposed action on climate change, including both GHG emissions and reductions from the proposed action (see below), and (2) the effects of climate change on the proposed action and its environmental impacts.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Leah K. Corrigan	19000	9	The DEIS does not provide an analysis of to determine if additional groundwater withdrawals associated with new water rights that will be required to implement the action alternatives, would infringe on the instream flow rights and wild and scenic nature of the EFSFR, the South Fork Salmon River and the Salmon River. The DEIS states this analysis will be performed by Idaho Department of Water Resources after a water rights application has been filed. However, the FS has a separate and independent obligation to analyze the potential cumulative impacts of the project, along with reasonably foreseeable actions authorized by the Forest Service and the impacts of climate change, on instream flow rights and wild and scenic values of the EFSFR, South Fork Salmon River and Salmon river. The FS should prepare a new or supplemental EIS that includes this analysis.	WTR	SDEIS Section 4.8.2.2 describes the water quantity effects of the Project including the effects of groundwater withdrawals associated with the diversion rates sought by Perpetua via pending water rights applications with the IDWR. The approved water rights would include measures protective of existing instream flow rights as enforced by the IDWR. The Forest Service initially protested Perpetua's water rights applications on this basis but resolved those protests through agreement on a mitigation measure to be incorporated into the water rights authorization.
Leah K. Corrigan	19000	10	The FS must improve the analysis of impacts on water quality and water quantity. It is not appropriate to defer this critical analysis to the Final EIS. The potential impacts of the project must be disclosed in the Draft EIS, at a point in the process where the public has the opportunity to comment. The FS must complete this analysis in a new EIS or a supplement to the EIS, and provide opportunity for public comment on this supplemental analysis.	WTR	The Final EIS analysis incorporates revisions per public comments received on the SDEIS water quantity and quality analysis. However, that SDEIS analysis was complete and did not defer any analysis to the Final EIS.
Leah K. Corrigan	19000	15	As discussed previously, the DEIS may be substantially underestimating the reductions in water quantity and quality that are likely to result from the action alternatives. If reductions in water quantity are larger than predicted, which is likely given the issues discussed above (e.g. the interactive impacts of the action alternatives and climate change), then both impacts on water quality and increases in water temperature, and resulting impacts on fish populations are likely to be much more substantial than indicated by the analysis provided in the DEIS. In addition, the SPLNT temperature models used in the DEIS stream temperature analysis do not account for changes to stream temperatures caused by changing climate conditions, and do not account for increased temperatures in the East Fork South Fork downstream of the mine site, even though the "Fisheries Analysis Area" encompasses downstream habitats and downstream temperature increases are likely. The NorWeST model, produced by the U.S. Forest Service Rocky Mountain Research Station, represents future stream temperatures, adding 1.1-2.0 degrees C in the years 2030-2059, and 1.0-3.0 2070-2099 to SPLNT modelled values. In addition, the DEIS does not provide adequate analysis of how reductions in water quantity or floods, could result in higher than anticipated concentrations of minerals and other toxic chemicals that may negatively impact fish species. Further, if stream flows are reduced to levels lower than predicted by the flawed hydrologic model, particularly during the time of year of natural low flows, fish may suffer from impacts associated with lack of dissolved oxygen and predation that aren't adequately disclosed in the DEIS.	WTR	The EIS includes monitoring and mitigation measures that would be required by the Project ROD to address water quality and quantity effects that vary from current predictions.
Karen Balch (North Fork Veterinary Service)	19228	6	Unhealthy habitats weaken the immune systems of life forms making them susceptible to various diseases with increased morbidity and mortality. Increasing temperatures accompanying climate change directly or indirectly impact habitats and magnifies the adverse effects of environmental toxins such as heavy metals in water ways. An estimated one-third of tundra swans refueling and migrating through Coeur d'Alene, Idaho, will die of heavy-metal toxicity ingested from lake vegetation. For most of the 20th century, mining waste was discharged into the Coeur d'Alene River and tributaries. In 2019, the US Department of the Interior and US Geological Survey completed the scientific investigations report titled: "Arsenic, Antimony, Mercury, and Water Streams near Stibnite Mining Area, Central Idaho, 2011-17." In short, this study documents altered stream configuration and habitat in the study area. Dangerous toxin levels for aquatic and human life are directly associated with documented levels of arsenic, free cyanide, lead, mercury, silver, and zinc, and antimony. Even this most recent USGS study, many years after the most recent active mining activity in the Stibnite area, identified harmful levels of arsenic, antimony, and mercury contamination in those local waterways. From a veterinary perspective, I find this profoundly disturbing knowing that waters contaminated with heavy metals are the relied-upon water source for fishes, amphibians, insects, birds, domestic livestock, domesticated pets, wildlife and people. Heavy metal contamination of water ways is an evitable consequence of mega-scale mining, whether historical or contemporary.	WTR	No further response required. General in nature or position statement.
Karen Balch (North Fork	19228	8	I have serious concerns about the resulting heavy-metal contamination in the East Fork South Fork Salmon River and all downstream flows that will inevitably be associated with any new commercial mining in the Stibnite area. Detrimental impact on our future recreation in and around any associated	WTR	No further response required. General in nature or position statement.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Veterinary Service)			rivers, streams, lakes, and reservoirs is truly secondary to the ongoing profound harm to impacted ecological systems. Ongoing heavy metal poisoning of rivers simply threatens the diversity and robustness of aquatic life (in particular protected fish) and, if eaten frequently enough, other life forms such as ospreys, waterfowl, and even humans.		
Karen Balch (North Fork Veterinary Service)	19228	14	Damage to water and water resources is among the worst environmental consequence of gold mining. As reported, gold mining in modern times is very destructive to water resources as evidenced in Nevada where there has been a huge gold mining industry. According to the US Geological Survey, some of the largest open-pit mines in northeastern Nevada have resulted in the water table dropping roughly 1,000 ft. in some areas. One gold mine may consume purportedly 100 million gallons per day. Water systems are commonly contaminated from cyanide, processing chemicals and acid mine drainage that runs off exposed rock. A Perpetua Official told me that 20 percent of the water for this project will originate from the East Fork South Fork Salmon River. Exactly how much water in quantity is that? And where is the other 80 percent coming from? During the Four Corners Fire of this year that occurred on West Mountain Road just across Cascade Lake, within a few days after initiating aerial attack an estimated 3.1 million gallons of water came from Cascade Reservoir; I have never seen that lake so low. I also adamantly oppose the use of Johnson Creek as the main route of transportation to the Stibnite Gold Project. Is it truly presumed that a toxic chemical spill, or diesel-gas spill couldn't happen on the first day or earlier that operations begin.	WTR	SDEIS Section 4.8.2.2 and Figure 4.8-3 describe the sources and amount of water that would be consumptively used by the Project. Position statement regarding the use of the Johnson Creek Route. No response required.
Olin Balch (North Fork Veterinary Service)	19234	2	Mining as proposed by the Stibnite Gold Project Supplemental DEIS profoundly threatens the quality and inherent safety of surface water and ground water. Contaminated water (containing arsenic, antimony, and mercury) in turn literally endangers all downstream aquatic species and their habitat, including ESA-listed Snake River Chinook Salmon, Snake River Steelhead Trout, and Columbia River Basin Bull Trout. Heavy-metal pollution starting at the headwaters of the East Fork South Fork Salmon River contaminates all downstream waters to the Pacific Ocean. ("The analysis shows that remaining rock in pit walls and the development rock, deposited in the TSF and pit back fills, would be largely non-acid generating, but would be capable of leaching aluminum, antimony, arsenic, cadmium, copper, manganese, mercury, zinc, sulfate and TDS into surface water and groundwater in concentrations that exceed water quality criteria. Therefore active contact water collection and water treatment would be required for a period of time during the operations and post-closure period until geochemical stability of mined materials could be achieved. In the case of the TSF where stabilization would depend on consolidation of tailings plus liner and cover installation over the tailing, this collection period would be approximately 40 years. USDA Stibnite Gold Project Supplemental DEIS, ES-14 – ES-15.)	WTR	No further response required. General in nature or position statement.
Olin Balch (North Fork Veterinary Service)	19234	5	I have serious concerns about the resulting additional heavy-metal contamination in the East Fork South Fork Salmon and all downstream flows that will inevitably be associated with any new commercial mining in the Stibnite area. Detrimental impact on our future recreation in and around any associated rivers, streams, lakes, and reservoirs is truly secondary to the ongoing profound harm to those associated ecological systems. Ongoing heavy-metal poisoning of rivers simply threatens the diversity and robustness of aquatic life (in particular protected fish) and, if eaten frequently enough, other life forms such as ospreys, water fowl, large and small aquatic wildlife, including humans.	WTR	No further response required. General in nature or position statement.
Joel Drake	19251	1	Please know that these comments and the information I have provided are unique. I reviewed hundreds of comments posted by others and only saw a few that briefly mention the large risks the Plan imposes on the water quality of Warm Lake. Please take time to thoughtfully review my comments and thoroughly consider my requested actions which are focused on protecting and preserving the water quality of Warm Lake.	WTR	No further response required. General in nature or position statement.
Joel Drake	19251	2	No Chemical Deicers (NaCl, MgCl, etc.) used within the Warm Lake drainage 1) The Plan and Draft EIS be revised to specifically state and contractually affirm that no chemical deicers will be applied to any section of Warm Lake Highway (Valley County road #10-579) to the East of Big Creek Summit.	WTR	The contents of agreements between Valley County and Perpetua are outside the purview of the Forest Service.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>2) Requirements in any Special Use permit issued by the Forest Service for transportation of materials to and from the mine site must specifically prohibit use of chemical deicers on the section of Warm Lake Highway (Valley County road #10-579) to the East of Big Creek Summit. With any violation of this prohibition serving as basis for immediate revocation of the USFS permit.</p> <p>3) Any Memorandum of Understanding (MOU) or Memorandum of Agreement (MOA) or other agreement between Valley County and Perpetua Resources for operations and maintenance of roads in the County shall specifically state and contractually affirm that no chemical deicers will be applied to any section of Warm Lake Highway (Valley County road #10-579) to the East of Big Creek Summit.</p>		
Joel Drake	19251	3	<p>Water Quality Monitoring - Periodic Sampling / Testing / and Public Reporting of Results</p> <p>4) The Plan and Draft EIS be revised to specifically state and contractually affirm that Baseline water quality values for Warm Lake and its tributary Warm Lake Creek (from its initial source at Landmark Summit to the creek's inlet at Warm Lake) will be independently secured and published before any stage of mine preparation or operations begins.</p> <p>5) Any Special Use permit issued by the Forest Service for transportation of materials to and from the mine site must require MONTHLY sampling / testing / and public reporting of water quality results for Warm Lake and its tributary Warm Lake Creek (from its initial source at Landmark Summit to the creek's inlet at Warm Lake) during the multi-year period that mine preparation, operations, and restoration is conducted. Sampling and testing should be conducted more frequently following any reported or suspected spill.</p> <p>6) Any permit issued to Perpetua Resources by the IDEQ (Idaho Department of Environmental Quality) concerning water quality must require MONTHLY sampling / testing / and public reporting of water quality results for Warm Lake and its tributary Warm Lake Creek (from its initial source at Landmark Summit to the creek's inlet at Warm Lake) during the multi-year period that mine preparation, operations, and restoration is conducted. Sampling and testing should be conducted more frequently following any reported or suspected spill. prepared and submitted: 01-10-23 Joel Drake Page 2 of 6</p> <p>7) A cognizant, lead agency for water quality impacts generated by the transportation of materials to and from the mine must be identified (presumably, this is IDEQ or a federal agency).</p> <p>8) The identified lead agency will directly conduct, or contract with a qualified third-party to perform, MONTHLY sampling / testing / and public reporting of water quality results for Warm Lake and its tributary Warm Lake Creek (from its initial source at Landmark Summit to the creek's inlet at Warm Lake) during the multi-year period that mine preparation, operations, and restoration is conducted.</p> <p>9) Public Reporting will include water quality measurements presented in table and graph format maintained and publicly accessible on the identified lead agency's website.</p> <p>10) Baseline and Monthly measurements are needed for these water quality attributes. [Note: these include the water quality measurements currently conducted in Valley County for Payette Lake and Lake Cascade] : a. Dissolved Oxygen b. Total Phosphorus c. Water Clarity (turbidity) d. Water Temperature e. Nitrogen f. Salinity g. Trace readings for Petroleum Distillates and Solvents</p>	WTR	Collection of baseline water quality data from Warm Lake Creek prior to the construction period has been added to the Water Resources Monitoring Plan. Additional sampling and analysis would be required following spill events as part of the spill response.
Joel Drake	19251	5	The SDEIS (Supplemental Draft Environmental Impact Statement) does not address risks to water quality for a uniquely sensitive, key waterway along the project's transportation route - Warm Lake and its tributary, Warm Lake Creek. Specifically, the SDEIS fails to identify impacts or provide clearly defined actions and countermeasures to sufficiently address spills of liquid hazardous materials (fuels, solvents, etc.) into the Warm Lake watershed.	WTR	SDEIS Sections 4.7.2.2 and 4.16.2.2 describe application of a Transportation Management Plan to minimize traffic incidents that potentially result in spills and the responses to those spills. The area covered by the Transportation Management Plan includes Warm Lake Road.
Joel Drake	19251	6	Warm Lake - a unique ecosystem reliant on clean, unpolluted water Warm Lake is the largest natural lake within the Boise National Forest, at a relatively small 420 acres. By comparison, Payette Lake is 5,000 acres and Lake Cascade is over 27,000 acres in size. Warm Lake's small size makes it many times more vulnerable to introduced pollutants. Even one spill of liquid hazardous materials into the Warm Lake drainage would be devastating.	WTR	No further response required. General in nature or position statement.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Joel Drake	19251	9	<p>The SDEIS does not establish quantifiable measures or identify baseline values to assess proposed impacts to water quality on Warm Lake or its tributary Warm Lake Creek.</p> <p>At a minimum, before this SDEIS or Section 402 or 404 permits could be approved for this project, the SDEIS and project transportation plan would need to be revised to include requirements for; prohibition on use of chemical deicers on the Warm Lake Highway anywhere East of Big Creek summit, monthly sample testing of water in Warm Lake Creek at its entrance to Warm Lake by a federal agency or independent third party engaged by a federal agency, monitoring and follow up action by a federal waterways agency to enforce water quality compliance when pollution levels are detected, and that test results must be formally published each month to provide for public review and ensure transparency. Test results should be published in table and graph form that evidence the absolute levels of pollutants in the water over time (salts, fuel, hazardous materials, etc.) and the historic trends in those levels month-to-month over the life of the project. Federal waterways agencies need this information to hold the project management's team accountable for mitigation and clean up actions necessary to protect and preserve the water quality of Warm Lake Creek and Warm Lake itself.</p>	WTR	Monitoring of Warm Lake and Warm Lake Creek has been added to the Water Resources Monitoring Plan.
Joel Drake	19251	11	<p>The level of risk for accidents and rollovers and the direct impact hazardous spills would have within this segment are self-evident when considering the natural terrain and configuration of the road. This section of road was constructed in the 1930's by the CCC, is not sufficiently crowned, and its turns are not sufficiently banked for modern, large truck configurations. This road segment traverses and crosses over the primary headwaters of Warm Lake at numerous points and has extreme grade (8+%) through many tight, low-speed switchbacks through a steep, narrow canyon where all waters collected by Warm Lake Creek flow directly into Warm Lake. Warm Lake Creek is the primary tributary to Warm Lake, providing over 90% of all flowing water to the lake. Note: Perpetua's recap of route miles within 100 feet of streams on SDEIS page ES-18 omits miles for this section of road, which if added (5-miles) would represent 43% of total miles (11.5-miles) within 100 feet of streams. The hazardous features and location of this road segment are clearly insufficient to ensure reliable, safe, contained daily transport of the tons of environmentally destructive toxic mining chemicals, liquid fuels / oils / lubricants / solvents, and mining ore proposed for shipment to and from the mining site year-round through extremely severe weather conditions, over the extended twenty-year period call for under the Plan. Table 4.6-1 on page 4-98 of the SDEIS identifies this 5-mile section as having 36% of total route miles affected by avalanche hazard and that 29% of total avalanche chutes within the entire route, further increasing risk for transit of liquid hazardous materials during winter months. Due to the unique, physical attributes of the canyon and the road, it is hard to comprehend how risks to water quality imposed by the Plan on this fragile, unprotected watershed can be sufficiently managed or mitigated by any reasonable level of investment in the reconstruction / reconfiguration of the road or use of existing spill containment technologies.</p>	WTR	The EIS text has been revised to describe the length of Warm Lake Road miles within 100 feet of Warm Lake Creek. Sections 3.16 and 4.16 describe road conditions and potential traffic limitations on this road.
Joel Drake	19251	13	<p>The Plan and SDEIS fail to demonstrate how water quality of Warm Lake can or will be protected and preserved. Again, even one spill of liquid hazardous materials into the Warm Lake drainage would be devastating with long-term impacts to the lake, its aquatic life, and its residents. Simply put, Risk introduced by the Plan and the SDEIS on this fragile, unprotected water resource is NOT ACCEPTABLE - the risk is simply TOO HIGH.</p>	WTR	SDEIS Sections 4.7.2.2 and 4.16.2.2 describe application of a Transportation Management Plan to minimize traffic incidents that potentially could result in spills and the responses to those spills. The area covered by the Transportation Management Plan includes Warm Lake Road.
Joel Drake	19251	15	<p>Acting within their authority and responsibilities called for under the CWA, the USACE / EPA / USFS are compelled to weigh this information and assess the great risk imposed on water quality in this pristine area by the Plan. The probability of and damaging impacts from spills are supported by information disclosed in the Plan itself. The SDEIS clearly cannot be accepted as drafted, and action to impose restrictions which sufficiently mitigate the risk to Warm Lake, or a decision to fully deny the Sec 402 and 404 permits sought by the Plan, must be made.</p>	WTR	No further response required. General in nature or position statement.
Alan Haslam (Vice President, Permitting, Perpetua	19325	88	<p>These discrete ranges out to several decimal places imply much more certainty and uniformity to water quality conditions than does, or will, exist. Please cite the source of these values to allow the reader to look more closely at the expected conditions.</p>	WTR	The presentation of predicted surface water analyte concentrations reflects the reporting in the Site Wide Water Chemistry report. This report is cited in Section 4.9. Citations are not utilized in the summary table.

Resources Idaho, Inc.)					
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	89	These general groupings by waterbody are not telling the full story for temperature. For example, in the EFSFSR, stream temperatures are near or below baseline by EOY12. At the TSF on Meadow Creek, temperatures are elevated compared to baseline, but in Meadow Creek downstream from East Fork Meadow Creek, temperatures substantially decrease relative to the baseline conditions during mine operations and closure/reclamation activities. Please refine these groupings to reflect these details.	WTR	Stream temperatures are described more fully in SDEIS Section 4.9.2.2. Table 2.8-1 provides a summation of the impacts predicted.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	90	Baseline East Fork SFSR Summer Max Temperature is (13.7 to 17.4); 2021 MMP Summer Max Temperature is (13.8 to 18.3); all mercury units are ng/L. Please revise.	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	643	"Cumulative effects associated with the SGP consider the range of existing and foreseeable activities and their potential effects with respect to surface water and groundwater quality." Please replace " existing and foreseeable " with " past, present and reasonably foreseeable "	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	644	" Gold Stallion Horse Heaven Project " - As noted in previous comments, please provide definition of RFFA and rationale for including this project, or remove it. 36 CFR 220.3 defines Reasonably foreseeable future actions as: Those Federal or non-Federal activities not yet undertaken, for which there are existing decisions, funding, or identified proposals. To our knowledge, the Stallion Gold Horse Heaven Project meets none of these criteria and therefore should be removed as an identified RFFA.	WTR	The Gold Stallion Horse Heaven Exploration Project has been publicly announced by its proponent and represents a reasonably foreseeable future action subject to a Forest Service decision.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	645	"The continuation of approved exploration activities at the SGP by Perpetua could cumulatively increase stream sediment levels resulting from surface disturbance and erosion." This should be characterized as a small potential cumulative impact as its scope and disturbance area is quite small. Same as was done below where it is stated that: "However, as described in the Golden Meadows Environmental Assessment, the exploration and subsequent reclamation activities would have only a small direct effect on wetland and riparian resources, as the disturbance footprint is confined to exploration holes."	WTR	The description of the size of the potential impact has been added to the EIS text.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	646	"Compared to the No Action Alternative, the 2021 MMP would remove additional legacy mining materials and further reduce their impacts on water quality but would also contribute new sources of mine waste material to the East Fork SFSR drainage." If the ASAOC will reduce legacy mining materials AND the 2021 MMP would remove additional legacy mining materials, then the result would be a beneficial cumulative impact - the reduction of legacy mining materials. Then when combined with the fact that the 2021 MMP would reduce constituent levels of arsenic and antimony, then there would also be a beneficial cumulative impact on water quality. Please include this information.	WTR	The conclusion regarding water quality has been added to the EIS text.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	647	"Compared to the No Action Alternative, the 2021 MMP would remove additional legacy mining materials and further reduce their impacts on water quality but would also contribute new sources of mine waste material to the East Fork SFSR drainage." New sources of mine waste in far more protective storage areas and technologies are not equivalent to legacy mining materials that were disposed without such storage protections. It is incorrect to imply that they are equivalent. Please revise to reflect this.	WTR	Acknowledgment of the design and regulatory controls on the new sources of mine waste material has been added to the EIS text.
Alan Haslam (Vice President, Permitting,	19325	648	"This would increase traffic on Johnson Creek Route during the mine operational and reclamation period, leading to potentially higher erosion rates from the road surface along the Johnson Creek Route.	WTR	Revision not accepted. The statement acknowledges the potential for road usage to affect erosion.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Perpetua Resources Idaho, Inc.)			" Please acknowledge in this statement that the use of binders and road resurfacing could lead to a net decrease of dust and erosion along Johnson Cr route.		
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	30	" <i>Though the Burntlog Route includes a greater number of stream crossings, the Johnson Creek Route includes greater proximity to water resources.</i> " The other information in this paragraph and further sections of the SDEIS indicates that Johnson Creek Route has more stream crossings. Please reconcile.	WTR	The inconsistent text has been removed.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	33	" <i>Compared to existing conditions, project operations are predicted to increase temperatures in West End Creek and the East Fork SFSR below the Yellow Pine pit area.</i> " Please include also a summary of instances where temperatures would be decreased: P.4-337: " <i>Water temperatures in the warmer summer and fall months in Meadow Creek downstream from East Fork Meadow Creek substantially decrease relative to the baseline conditions during mine operations and closure/reclamation activities (Mine Year 6 through Mine Year 18), though there is an increase at Mine Year 27, which then continues to decline until Mine Year 112.</i> " P.4-337: " <i>The East Fork SFSR between Meadow Creek and YPP experiences decreases in summer maximum water temperatures relative to baseline conditions. There is a slight increase in temperatures, still lower than baseline, after Mine Year 22 once the low-flow piping along the TSF is removed, and temperatures continue to decrease once the revegetation efforts take effect.</i> " P.4-357 to 4-358; Table 4.12-6: <i>All Temperature WCI changes are negligible or beneficial (i.e. temps remain relatively consistent or drop) for all stream segments across the life of the project.</i>	WTR	The Executive Summary text has been revised to also include instances of cooler surface water temperatures.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	34	"...while formation of the West End pit lake raises temperatures in West End Creek. " West End Creek is not a flow through feature of the West End pit. Please revise.	WTR	The text has been revised to "... while surface water diversion to mine the West End Pit raises temperatures in West End Creek."
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	35	"...predicted temperatures return to existing conditions over a period of approximately 100 years. " Please clarify that this time period only applies to the stream reaches on the TSF. In the EFSFSR below YPP, stream temperatures are near or below baseline by EOY12. In Meadow Creek downstream from East Fork Meadow Creek, temperatures substantially decrease relative to the baseline conditions during mine operations and closure/reclamation activities. Temperatures in the EFSFSR above YPP are similar to or below baseline through out the project.	WTR	The clarification for the location where surface water temperatures return to existing conditions over a period of approximately 100 years has been added to the Executive Summary text.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	36	" <i>Surface water quality also could be impacted by increased sedimentation associated with mining activities, access road construction and use, and the construction and maintenance of required utilities, with the greatest potential for in-stream impacts occurring during times of higher overland flow.</i> " This statement is contradicted by Chapter 4 conclusions (included below) which state the potential for increased sediment associated with roads outside the mine site, but likely reduction to sediment within the mine site thanks to restoration of Blowout Creek in EOY -1. Please revise this statement to be consistent with the effects analysis conclusions. P.4-341: " <i>With the application of sediment reduction BMP's and surface runoff minimizing design techniques, the impacts of sediment in surface water to fish are predicted to be measurable but not severe, limited to the mine area, and occur during the active mining period. However, the restoration efforts in the EFMC would result in a substantial decrease in sediment input into Meadow Creek and the East Fork SFSR.</i> "	WTR	The description of sediment reduction has been added to the Executive Summary.

Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	37	"However, the 2021 MMP would have direct permanent impacts on water quality, as it would contribute new sources of mine waste material to the East Fork SFSR drainage." Please replace " would " with " could " as planned active water management should prevent this.	WTR	Revision not accepted. The section pertains to surface water and groundwater which would be affected by modified groundwater conditions that would contribute to surface water conditions.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	38	"Despite analysis area improvements to water quality as a result of the removal and reclamation of legacy mine wastes, exceedances of the most stringent water quality standards (including both human health and aquatic life) for water column antimony, arsenic, copper, and mercury are anticipated." Please qualify this statement with information regarding where and how long exceedances may occur. This statement appears to contradict the statement on pg ES15 regarding As, Hg, and Sb concentrations being "comparable to or less than the existing conditions."	WTR	A description of these predicted concentrations being comparable to existing conditions has been added to the Executive Summary.
Ruth Lewinski	19378	5	2.0 Unsafe/Unpredictable Contaminant Values in Water, Air and Soil Quality In many of the courses that I have taken, calculations for Chemicals of Concern have had somewhat standardized calculations, with a range/ standard deviation in predictive values. The MMP 2021 Water Chemistry Tables Tables 4.9-12 through 15 and 18 through 20 show predicted concentrations of various metals and other chemicals in West End, Midnight, Hangar Flats, and Yellow Pine Pits and Pit Lakes extrapolated out to 100 or 112 mine years. Interestingly, most sites also are projected to have no remaining toxins after 'mine-year' 40. I question the accuracy of these calculations, especially as comments elsewhere in the SDEIS indicate that there will be continued levels of contamination. The current predominant toxins currently are arsenic, antimony, and mercury. I understand that these calculations are based on a modeled program in which the mine-pits no longer release water after the operation of the mine (year 40). However, in most standardized equations, there is an 'uncertainty variable' that accounts for errors, leaks, changes in time/operation and reaccumulation of contaminants in downstream areas. Often, there is also a model outlier that discloses potential events from a natural disaster, such as an earthquake or avalanche, which happen frequently in central Idaho. The Preferred Alternative evaluated by the Forest Service relies on SGP assertions that Perpetua will adhere to the 2021 MMP, with an assertion that it will operate at 29% capacity. Perpetua has a PTC to construct a facility capable of operating at 180,000 tons/day capacity and an amendable permit condition limiting production to 135,000 ton/day (75% of capacity), There are no provisions in the PTC permit conditions to limit SGP to the Forest Service assumed production level. IDEQ permit conditions allow production up to the 75% of capacity TRACT limit, and is amendable without federal oversight. COMMENT: Please provide calculations used for modeling outcomes in addition to modeling factors of uncertainty as well as projection of values at the pump facility operating at 75% vs 29%.	WTR	SDEIS Section 4.9.2.4 describes the model uncertainty associated with water quality predictions. Details on modeling calculations and the modeling input files are included in the Site Wide Water Chemistry Report (SRK 2021b) which was cited in the SDEIS and released in its entirety at the same time as the SDEIS. The Forest Service decision on the SGP is based on the Project as described in the 2021 MMP and reasonably foreseeable future conditions. Worst case scenarios are not required to be analyzed. Compliance with the Forest Service decision requires adherence to its approval conditions.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	137	H. Water rights and consumptive uses Perpetua has four existing water rights for the project, and has applied to the Idaho Department of Water Resources for four new water rights and four water right transfers. The largest water right that Perpetua seeks would divert up to 9.6 cubic feet per second (CFS) of surface or groundwater from the East Fork South Fork Salmon River (EFSFSR). Additionally, Perpetua proposes to divert rain and snowmelt to use for ore processing. Under Idaho law, a water right is not required if the water is diverted prior to entering a "natural channel" or "watercourse." That is the case even where the rain or snowmelt would otherwise flow into the EFSFSR or contribute to groundwater recharge. As disclosed in the SDEIS, there are at least two minimum instream water rights that exist downstream of the proposed project: an instream minimum flow water right held by the state of Idaho to preserve fish and wildlife, scenic and recreational values, and to protect and enhance water quality; and a federal-reserved Wild & Scenic water right on the main Salmon River. However, the impact to these surface water rights were not sufficiently analyzed in the SDEIS. First, with respect to the state's instream minimum flow rights, the SDEIS discussed the potentially impacted minimum stream flows are	WTR	Predicted surface water flows following the diversion of water associated with the Project are described in SDEIS Section 4.8.2.2. Most flow reductions occur in the Project area and decrease downstream due to the inflows from surface water and groundwater not affected by the Project. Flow reductions below the East Fork SFSR confluence with Johnson Creek are less than one percent of mean flows. As described in SDEIS Section 3.8.3, IDWR is responsible for the administration of water rights and for mitigation requirements. The Forest Service is engaged in the IDWR permitting process regarding the mitigation requirements.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>subordinate to domestic, commercial, municipal, and industrial (DCMI) uses, and up to 8.2 cfs of new non-DCMI uses. SDEIS at 4-174. The SDEIS also discloses that the maximum diversion rate under existing and proposed surface water rights is approximately 20 percent of the base flow in the EFSFSR. Id. However, this section does not provide any flow data for either the state or federal minimum streamflow water right, nor does it provide usage periods and affiliated diversion rates for the EFSFSR. All this information is necessary for a realistic analysis of whether the minimum streamflow water rights are likely to be negatively impacted and, if so, what the impact to their values will be.</p> <p>Second, the Forest Service has an obligation under the Wild & Scenic River Act to protect outstanding remarkable values (ORVs) of the Wild & Scenic stretch of the Salmon River. There is no analysis of the potential impact Perpetua's proposed water rights applications might have on the federal reserved water right, and thus impacts to the ORVs on this stretch of the Salmon River, specifically between the South Fork Salmon/Main Salmon confluence and Long Tom Bar. Perpetua's own water right application indicates that mitigation may be required to protect such values. But the SDEIS leaves the analysis to the Idaho Department of Water Resources to do despite the fact that the state law's subordination provisions subordinate the federal water right to industrial uses such as mining. Id. at 4-175.</p>		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	138	Third, the National Forest Management Act requires that the Forest Service manage rivers found eligible for designation to protect the values that provide the basis for their suitability for inclusion in the system. The South Fork Salmon River was identified as a suitable river. The SDEIS failed to analyze the potential impacts of the water right applications on the management and ultimately suitability for inclusion in the Wild & Rivers Act system.	WTR	The eligible rivers for inclusion in the Wild and Scenic Rivers Act system in the Project area are the South Fork Salmon River at the Warm Lake Road crossing, Burntlog Creek, and a 2.9 mile segment of Johnson Creek. The potential impacts to WSRs are discussed in Section 4.23.2. The Project is not expected to affect stream flow volumes or water rights in these streams.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	139	Fourth, there is no analysis of the impact to the minimum streamflow water rights due to the combination of the proposed water rights and the capture and diversion of contact water to ore processing that does not require a water right under state law, but that the SDEIS admits would otherwise flow into the EFSFSR. See id. at 4-150 ("Capture of contact water for consumptive use would reduce the volume of runoff and hence, stream flow..."). In fact, the SDEIS incorrectly assumes that the diversion, storage, and beneficial use of contact water requires a water rights permit from the Idaho Department of Water Resources (IDWR) prior to use. See SDEIS at 2-66 ("Any contact water beneficially used in the ore processing or for dust control or stored for more than 24 hours then treated and discharged would require water rights permitting through the IDWR prior to use."). IDWR, however, has recently determined--specifically in the context of Perpetua's water right application--that it does not have jurisdiction to review or issue a water right for the diversion of the contact water (or what IDWR has termed "diffuse water") because Perpetua has claimed that the contact water will not enter a "watercourse" prior to its diversion. See In the Matter of Application for Permit No. 77-14378 in the Name of Perpetua Resources Idaho, Inc., Interlocutory Order Deciding Questions of Law at pg. 12 (Aug. 19, 2022). IDWR's stated lack of jurisdiction to issue a water right permit for the diversion of contact water is regardless of whether or not the contact water would have, if not otherwise diverted, entered the EFSFSR or become part of groundwater resources. It is unclear, based on this false assumption, how much the SDEIS analysis relies on the state water right permitting process to ensure that the use of water resources are accounted for in the impacts analysis. This issue needs to be clarified in the SDEIS.	WTR	The predictive assessment of stream flows includes the effects of contact water collection as described in the water quantity conceptual model (SDEIS Figure 4.8-1). The assessment predicts resulting streamflows based on the diversion of contact water flow. Chapter 2 of the EIS has been updated to reflect the IDWR determination.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	140	<p>Finally, the SDEIS water rights section fails to mention the potential impact the water diversions might have on federally protected treaty fishing rights to the Nez Perce Tribe, rights that may not be protected or even considered through the process of securing water rights under the state's water right permitting process.</p> <p>Because of the missing information and incorrect assumptions, the SDEIS lacks a true analysis of the water rights, and thus does not and cannot propose mitigation to lessen potential impacts. Further analysis of the impacts to other water rights--including those held by the United States--and natural resources are the responsibility of the Forest Service and should be disclosed in this environmental analysis during the NEPA process.</p>	WTR	Potential effects of the Project on treaty fishing rights are described in SDEIS Section 4.24.2.2 in the Tribal Rights and Interests section.

Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	160	<p>1. Overall arsenic burden</p> <p>An estimated 616,000 - 1,856,000 tons (average - 95th percentile) of arsenic will be mined in the SDEIS preferred alternative. Approximately 36% of site-wide arsenic (102,560 - 827,600 tons) is in Development Rock (DR) and historic overburden, and 64% (309,580 - 1,028,400 tons) in ore. Practically all of this arsenic will be disposed of on-site or released to the immediate environment. Three principal concerns associated with this disposal are arsenic in air from mining dust, impacts to groundwater and meteoric waters in locations where DR is disposed, and in ores disposed in the Tailings Storage Facility (TSF) after gold extraction. Over time, all three sources will inevitably release arsenic to the local environment (Table SD3 in SDEIS).</p>	WTR	Effects of arsenic contained in mined materials with regard to air quality (Section 4.3.2.2), water quality (Section 4.9.2.2), and the tailings storage facility (Section 4.2.2.2) are discussed in the SDEIS. Predicted releases of arsenic and other constituents are included in those impact analyses.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	163	<p>4. Arsenic in development rock</p> <p>Under the SDEIS preferred alternative, the TSF embankment and buttress will contain an estimated 115,317-425,957 tons of arsenic, 117-378 tons of mercury, and 13,145-17,566 tons of antimony (average - 95th percentile). Approximately 50% of DR arsenic will be disposed of in surface repositories and 50% in pits. Pit-disposed COCs will be exposed to groundwater wet/dry and redox cycles, and will release COCs to groundwater. Although additional protections will be afforded from meteoric waters, YPP disposal of COCs increases by 25% with similar increases in discharge to groundwater expected. Potential releases of COCs from DR to groundwater and consequent downstream effects should be re-evaluated by the Forest Service in a revised SDEIS.</p>	WTR	SDEIS Section 4.9.2.2 describes the releases of arsenic and other constituents due to interaction of groundwater with development rock in Tables 4.9-13, 4.9-14, and 4.9-15. The effects of groundwater discharge to surface water are incorporated into the predicted surface water analyte concentrations presented in Tables 4.9-18 through 4.9-21 and Figures 4.9-22 through 4.9-25.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	183	<p>2. Impacts to water quality from ROW infrastructure</p> <p>Numerous components compose the ROW infrastructure, including line towers, access roads and associated gates, and concrete tower support pads. While much of the transmission line construction will take place using helicopters to set the towers and string line, a significant amount of "on-the-ground" work is still required to update or construct the proposed transmission lines associated with the SGP. Further, the modification or construction of either proposed access route will require the use of heavy equipment. Many of the proposed construction activities will take place near surface water bodies.</p> <p>Construction of the transmission lines will also contribute significant amounts of sediment to the waters of the United States, which will further impact fisheries habitat and directly impact sensitive fish eggs and reproductive success. This is particularly evident along the proposed new transmission line at the bottom of Riordan Creek where, based on our geologic analysis, there is a recent history of slope instability and sediment movement following wildfires. These potential impacts exponentially increase when one takes into consideration locations where transmission line rights-of-way intersect with access roads or routes associated with the SGP. Please see our Specialists comments on sedimentation and the impacts to the environment, which are included as an appendix to this document (Newberry 2022, Item #13, pp. 45-53) and are summarized in our Executive Summary.</p> <p>Of the 37 streams within the APE, 11 are listed by the Idaho Department of Environmental Quality as impaired, primarily for phosphorus contamination, sedimentation, and water temperature. While the transmission towers themselves will not contribute to sedimentation and the transmission lines and associated activities will not likely affect phosphorus levels, the proposed activities will likely affect stream temperatures through vegetation removal and management at the crossing locations. Further, construction or line installation/upgrade equipment will likely cross streams at line access roads, between towers along the transmission line ROW, but the impacts remain unaddressed in the SDEIS. We are particularly concerned about impacts to Burntlog Creek and Johnson Creek, which are eligible Wild and Scenic Rivers. The SDEIS provides no mitigation measures designed to limit these potential impacts.</p>	WTR	SDEIS Section 4.9.2.2 describes the effects of the SGP and associated infrastructure on water quality, including erosion and sedimentation. Design features and Forest Service requirements for infrastructure development limit the effects on water quality. Vegetation removal along power lines affects localized areas of streams where the infrastructure crosses a channel. This localized modification to the vegetation is not expected to materially alter stream flow temperature.
Bonnie Gestring (Northwest Program Director,	17634	192	The Forest Service/Perpetua should also anticipate and have contingency plans at the mine site and at the water treatment facility if power is interrupted for long periods of time.	WTR	<p>Contingency plans for power outages are part of the water treatment plant design and approval under the Idaho State IPDES permit.</p> <p>An associated mitigation measure has been added to Section 4.9.3 of the Final EIS.</p>

Earthworks) and seven others					
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	200	<p>10. No current road sediment production data was gathered, and no project monitoring methods were described for road sediment generated during use by the mine</p> <p>Sediment generated from existing roads, from construction and reconstruction of roads, and use of roads has been a major problem for fish and fish habitat in granitic streams for over 50 years. Several methods to model this sediment exist and have been a mainstay in FS project documents. The SDEIS does not show the use of any modeled sediment for the reconstruction or use of Johnson Creek and Stibnite roads, or the use, reconstruction of 20 miles of the Burnt Log Road, and the new construction of 15-20 miles of the Burntlog Route. This should be used as a comparison between alternatives. No data collection over time was shown in the SDEIS. Sediment changes in the substrate were not modeled or shown in the SDEIS as a monitoring tool to show changes in the fish habitat especially of Burntlog Creek, Trapper Creek, Riordan Creek, Johnson Creek and the East Fork South Fork Salmon River.</p>	WTR	Design features and Forest Service requirements for road construction and maintenance would be incorporated into the Project resulting in sediment generation consistent with approved Forest Service roadways.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	204	<p>14. Burntlog Route and associated roads and ROWs will contribute significant sediment to waterways</p> <p>As is documented in the Fisheries, Recreation, Soils and Reclamation, and Water Quality Specialist Reports associated with the SGP and SDEIS, and further supported by our own analysis and comments (Newberry 2022), the Burntlog Route and the associated Thunder Mountain Connector Road will contribute a significant amount of sediment to Burntlog, Trapper, Trout, Cabin, and Riordan creeks. During the Burntlog Route construction, including bridge and culvert installations, the potential exists for increased runoff, erosion, and sedimentation resulting from localized vegetation removal and soil excavation which could result in increased sediment load in streams. Construction of and upgrades to access roads creates a potential for increased runoff, erosion, and sedimentation as a result of localized vegetation removal and excavation of soil, rock, and sediment, which could result in increased sediment load in streams. Expected permit stipulations from IDWR and IDEQ would ensure streambank vegetation would be protected except where its removal is necessary. New cut or fill slopes not protected with some form of stabilization measures would be seeded and planted with native vegetation to prevent erosion. Use of temporary erosion and sediment control BMPs also would be employed.</p> <p>We are concerned that Perpetua has not proposed any fish habitat or sediment monitoring stations near the Burntlog Route extension. Further, there are no erosion monitoring sites for the proposed Trapper Creek and Riordan Creek headwater stream crossings, nor for the Cabin/Trout (FR 467) road in Cabin Creek and Trout Creek when 1.6 miles of avalanche hazards were recognized (Fig. 3.2-6; p. 3-29) in the transmission line and OSV reconstruction with bull trout and Chinook salmon and steelhead habitat downstream of this road.</p> <p>We believe that without these critical monitoring site locations, neither the Forest Service nor Perpetua will be able to accurately assess the impacts to water quality and fisheries from sediment delivery. This becomes even more critical from the point the existing Burnt Log Road ends, and increases from that point towards the mine site. This is directly attributable to the region's erosive geology, which becomes more erosive nearer the SGP mine site. Further, the highly erosive local granite has yet to be tested and quantified for hardness, and is likely inappropriate for use during Burntlog or other road/route construction as it would contribute to sediment rather than contribute to sediment or dust control when placed on roadbeds.</p>	WTR	Sediment monitoring is required in the Project area as part of an approved Water Resources Monitoring Plan.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	217	<p>In addition, the Cabin Creek route includes seven stream crossings. OSV use has the potential for releasing burned and unburned fuel and lubricants into the environment, which can result in adverse impacts to water quality and alter snowmelt patterns. Research has shown that snowpack concentrations of ammonium, sulfate, toluene, xylene, and benzene are positively correlated with snowmobile traffic. When the snow melts, these pollutants, which are stored in the snowpack throughout the winter, are released in a concentrated pulse.</p>	WTR	<p>OSV usage has the potential to release fuel and lubricants to snowpack. However, concentrations of these constituents rapidly decrease with distance from roadways as reported by the USGS in their 1999 study at Yellowstone National Park.</p> <p>The EIS has been revised to describe this potential effect and its OSV route-related spatial nature.</p>

David Chambers	17634-A	8	<p>2.4.7.13 Post Closure Water Treatment Post-closure water treatment, if required, typically doubles the amount of financial assurance required for a mine. For the Stibnite Project, the requirement for post-closure water treatment depend on two potential sources of contaminated water; (1) pit lake water in the West End Pit could exceed discharge water quality standards (SDEIS 2022, Section 2.4.7.5); and, (2) consolidation water from the tailings, and any ongoing seepage from the waste rock buttress (SDEIS 2022, Section 2.4.7.6).</p> <p>According to the SDEIS, water treatment will no longer be required after Mine Year 40 (SDEIS 2022, Section 2.4.7.6). In order for this to occur, water treatment would no longer be required for the West End Pit, and the seepage from the tailings consolidation and from any buttress seepage would need to be de minimis.</p> <p>The estimate for consolidation of the tailings, along with the cessation of seepage, at Mine Year 40 appears to come from the Tierra Group (2020). This reviewer is familiar with one lined mine waste impoundment, the New World waste facility in Montana, where waste consolidation water has continued to accumulate since the impoundment was sealed, necessitating the annual pumping and disposal of accumulating water. This is probably due to liner leakage, but a definitive source of the accumulating water at New World has not been identified. All liners leak – it’s just a matter of how much.</p> <p>The Stibnite TSF Buttress contains a large amount of non-potentially acid generating material, and some potentially acid generating material (SDEIS 2022, p. 4-191). All of this material can leach antimony, arsenic, cadmium, chromium, copper, fluoride, manganese, mercury, nickel, lead, selenium, silver, sulfate, thallium, zinc, and total dissolved solids above surface water quality standards (SDEIS 2022, Table 4.9-3). The predictions are that the seepage will exceed groundwater quality standards for antimony and arsenic (SDEIS 2022, Table 4.9-4).</p> <p>Low Grade Ore stockpiles could be left at mine closure. The seepage from any residual log grade ore would be worse than from the other waste in the buttress. Water quality modeling assumed the Low-Grade Ore would be processed prior to mine closure, but there is no guarantee this will happen.</p> <p>The waste rock in the tailings dam buttress will have a liner on top, but no liner on the sides or bottom. A top liner is a good idea, but it does not guarantee de minimis seepage after the initial drain down of the waste. It is quite likely that seepage from the waste rock could exceed the 5% infiltration of incident water assumed in the SDEIS. Any seepage will contain high contaminant levels of antimony and arsenic.</p> <p>The actual infiltration rate and contamination loads can only be established by actually measuring seepage rate and contaminant levels post-closure, once all reclamation activities are complete.</p> <p>The assumption for the SDEIS appears to be that there will be no seepage from the tailings after initial seepage drain down. In the SDEIS, it is noted; “From Mine Year 41 onwards, it is expected that consolidation would be complete and pore water drainage from the tailings would cease (Brown and Caldwell 2021b).” (p. 4-207)</p> <p>The interpretation of little to no post-closure seepage is supported by the data presented in Figure 4.9-3 Tailings Storage Facility Buttress Seepage Volume (SDEIS 2022), which shows the pop-out seepage and toe seepage going to zero after the liner is installed. In Figure 4.9-6 Tailings Storage Facility Seepage Volume (SDEIS 2022), cover infiltration and consolidation water are essentially zero after Mine Year 40.</p> <p>Until an actual post-closure seepage rate can be established for both tailings drain down and buttress seepage, it is not reasonable from a public-liability perspective to assume seepage from the waste rock in the buttress will be low enough, and/or contain only low levels of contaminants, that there is no possibility that long-term treatment might be required. Provision for water treatment in perpetuity should be assumed until it can be demonstrated by post closure monitoring that water treatment will not be required beyond Mine Year 40.</p> <p>If water treatment is needed for the West End Pit water, neither the need for, or the length of time required, has been established in the SDEIS. However, since the potential for Wend End water treatment</p>	WTR	<p>Uncertainties regarding the long-term water quality predictions are described in SDEIS Section 4.9.2.4 with mitigation measures to address those uncertainties described in SDEIS Section 4.9.3.</p> <p>The assumptions utilized for reclamation cost estimates and the establishment of closure bond amounts are determined by the Forest Service in an administrative process that recognizes potential uncertainties and the need for monitoring and updating in response to observed changes in facilities and facility closure.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>has been identified, financial provision for West End Pit water treatment should be provided in the postclosure financial assurance.</p> <p>The point to take from these concerns for the need for potential long-term water treatment is that there is significant uncertainty in the potential requirement for water treatment. Only empirical data collected post closure will confirm or deny this assumption. Geochemical and hydrological predictions covering post closure are not accurate enough on which to base major decisions.</p>		
Samuel Penney (Chairman)	19396	15	<p>Clean water is vital for the Tribe's cultural, spiritual, and economic uses. The Tribe has a vested interest in protecting water resources both on the Nez Perce Reservation and in its treaty territory throughout the Clearwater, Snake, Salmon, and Columbia river basins. As part of the foundation of Nez Perce history, the Earth (wéet'es) itself was pulled out of the water (kúus) by "the old man" (qíwn), as the first step in the creation process and has significant spiritual importance to Tribal members. Clean water is materially essential in contemporary tribal life as well, providing a home for the fish that are central to tribal cultural identity, and also in its role as important healing medicine that is consumed at the beginning of traditional dinners and utilized in the sweathouse.</p> <p>The Nez Perce have always revered the purest, direct sources of water in their lands, with seeps, springs, and cold mountain streams being very important. The United States has a general trust responsibility to protect tribal lands, assets, and resources and these include the water that flows over and through tribal lands and the natural resources that depend on that water.</p>	WTR	No further response required. General in nature or position statement.
Samuel Penney (Chairman)	19396	34	<p>The existing conditions section does not characterize and describe the existing geochemical conditions or provide information as to the present contributions of and impacts from existing sources and/or discharges of contamination on baseline water quality within and adjacent to the Project area. In addition to the Yellow Pine/Pit Lake there are five adits or tunnels, three sources of waste rock, three sources of tailings or spent heap leach piles, and a mill and smelter site that the U.S. Environmental Protection Agency ("EPA") has identified as being sources of contamination at the Project site.</p> <ul style="list-style-type: none"> In DEIS Section 3 Affected Environment, the Yellow Pine Pit Lake is identified 79 times. However, it is only identified in terms of its impact as a barrier on existing fisheries, with the following exceptions. Section 3.2.3.3 Legacy Mine Features identifies it as a legacy mine feature. Section 3.5.3.3.4 Soils and Reclamation Materials identifies it as a past mine activity where little or no soil cover is present. Section 3.8 Surface Water and Groundwater Quantity identify it as a surface water feature, and it is identified in Section 3.11 Wetlands and Riparian Resources. Outside of Section 3.12 Fish Resources and Fish Habitat, the only other mention is in Section 3.18 Public Health and Safety where it is mentioned as part of a past public health assessment. 	WTR	<p>SDEIS Section 4.9.4.5 describes the geochemical conditions of the existing Yellow Pine pit lake.</p> <p>The historical adits are depicted on Figure 3.9-6 with their geochemical implications captured by the surface water sampling and characterization described in SDEIS Section 3.9.4.3 and Figures 3.9-7 through 3.9-10.</p>
Samuel Penney (Chairman)	19396	35	<ul style="list-style-type: none"> The EPA and Tribe have identified five different adits and/or tunnels that are sources of contamination at the Project site: (1) Bailey Tunnel; (2) Bonanza Adit; (3) DMEA Adit (includes DMEA Waste Rock Dump); (4) Meadow Creek Mine Adit; and (5) Monday Tunnel/North Tunnel/Cinnabar Tunnel. SDEIS Section 3.2.4.3 Legacy Mine Features only identifies the Bailey Tunnel and Monday Tunnel as legacy mine features. The DEIS does not characterize and describe the existing geochemical conditions or provide information as to the present contributions of and impacts from existing contamination from the adits and tunnels that have been identified at the Project that impact existing baseline water quality. 	WTR	<p>The five adits were incorporated into the baseline characterization of surface water conditions.</p> <p>The historical adits are depicted on Figure 3.9-6 with their geochemical implications captured by the surface water sampling and characterization described in SDEIS Section 3.9.4.3 and Figures 3.9-7 through 3.9-10.</p>
Samuel Penney (Chairman)	19396	36	<ul style="list-style-type: none"> EPA has identified the following waste rock piles as sources of contamination at the Project site: (1) NW Bradley Dumps & Hennessy Creek; (2) Bradley Mancamp Dumps; and (3) Bradley Northeast Oxide Dumps. SDEIS Section 3.2.4.3 identifies the Bradley Dumps as legacy mine features. SDEIS Section 3.7.4.3 identifies a portion of the Bradley dumps as part of the removal actions and Section 3.9.4.3 identifies the Bradley dumps as having a geochemical influence. The SDEIS does not characterize and describe the existing geochemical conditions or provide information as to the present contributions of and impacts from existing contamination from the waste rock piles that have been identified at the Project that impact existing baseline water quality. 	WTR	<p>The historical surface facilities were incorporated into the baseline characterization of surface water conditions.</p> <p>The historical adits are depicted on Figure 3.9-6 with their geochemical implications captured by the surface water sampling and characterization described in SDEIS Section 3.9.4.3 and Figures 3.9-7 through 3.9-10.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Samuel Penney (Chairman)	19396	37	<ul style="list-style-type: none"> EPA has identified the following tailings piles as sources of contamination at the Project site: (1) Keyway Dam/Keyway Marsh; (2) spent ore disposal area and Bradley Tailings; and (3) Hangar Flats (Pioneer) Tailings Pile and Hecla Heap Leach. The Keyway Marsh is identified as a seep in Table 3.9-7. SDEIS Section 3.9.4.3 Geochemical Influence of Historical Mine Wastes notes dissolved antimony concentrations in Meadow Creek increase from an average of 0.32 µg/L at YP-T-33 above the spent ore disposal area (Figure 3.9-7) to 6.1 µg/L at YP-T-27 below Keyway Marsh. The water quality of nearby seeps associated with the Bradley tailings, spent ore disposal area, and Keyway Dam also was elevated in metals, an indication that historical mining features are impacting the alluvial and bedrock aquifers. The spent ore disposal area and Bradley Tailings are also mentioned elsewhere in Section 3. The Hangar Flats Tailings are not identified in Section 3. The Hecla Heap Leach is identified in Sections 3.2.4.7, 3.9.4.2 and 3.18.4.1 as a historic mine feature. <p>The existing conditions section does not characterize and describe the existing geochemical conditions or provide information as to the present contributions of and impacts from existing contamination from the tailings and heap leach piles that have been identified at the Project that impact existing baseline water quality.</p>	WTR	<p>Tailings in the Hangar Flats area are identified on Figure 3.9-6.</p> <p>SDEIS Section 4.9.4.5 describes the geochemical conditions of the existing Yellow Pine pit lake.</p> <p>The historical adits are depicted on Figure 3.9-6 with their geochemical implications captured by the surface water sampling and characterization described in SDEIS Section 3.9.4.3 and Figures 3.9-7 through 3.9-10.</p>
Samuel Penney (Chairman)	19396	38	<ul style="list-style-type: none"> EPA identified the Meadow Creek Mill and Smelter as a source of contamination. The SDEIS identifies mill and smelter sites that have been remediated in the past but not specifically the Meadow Creek Mill and Smelter. The existing conditions section does not characterize and describe the existing geochemical conditions or provide information as to the present contributions of and impacts from existing contamination from the Meadow Creek Mill and Smelter have been identified at the Project that impact existing background water quality. 	WTR	<p>Surface water sampling locations used to characterize surface water quality affects associated with historical mined materials including the mill and smelter are shown in the inset on Figure 3.9-7. Further details regarding these samples and analyses are included in the referenced Surface Water Quality Baseline Study (HDR 2017f).</p>
Samuel Penney (Chairman)	19396	45	<p>2.4.5.10 Surface Water and Groundwater Management</p> <p>In Table 2.4-10, The total estimated gross fresh and recycled water usage being 4,431 gallons per minute (“gpm”), with “ore processing facility operations representing approximately 97 percent of water use associated with the SGP.”92 A water right of 9.6 cubic feet per second (“cfs”) (4,308 gpm) was also applied for, yet the SDEIS states that the majority of the water needed for ore processing would be recycled from the TSF. If that is the case, please explain why the water right application amount is so high?</p>	WTR	<p>Diversion of water for consumptive use by the process is required to build sufficient water inventory in the mill process and tailings storage facility to allow subsequent water recycling. Thereafter, ore processing would require make-up water to maintain its water balance by replacing water lost to evaporation during processing and from the tailings storage facility plus water entrained within the tailings material stored in the tailings storage facility.</p>
Samuel Penney (Chairman)	19396	85	<p>3.8 Surface Water and Groundwater Quantity</p> <p>SDEIS Section 3.8 summarizes the existing conditions of groundwater and surface water hydrology at the SGP and surrounding areas. As noted in the SDEIS, the SGP and surrounding area “consists of mountainous terrain dissected by typically narrow valleys with steep slopes” and “[t]he hydrology of the analysis area is strongly influenced by seasonal patterns of snow accumulation during the winter, and snowmelt in the spring and early summer.” Despite the apparent water-scarcity of the area, the SGP will require large amounts of water for ore processing, dust control, and other uses to support mining operations. Approximately 2.2 pounds of gold requires, on average, 70,000 gallons of water to produce.</p>	WTR	<p>Comment noted. Statement of position. No response required.</p>
Samuel Penney (Chairman)	19396	86	<p>The SDEIS notes that Perpetua’s existing water rights are valid, however, “the specific points of diversion, place of use, and beneficial use [do] not reflect planned SGP activities and [will] need to be adjusted through the transfer process, and through filing additional applications for permit.” The SDEIS points out that it is the responsibility of Idaho Department of Water Resources (“IDWR”) to “ensure enough water is available for the water right and that the oldest (senior) water rights are satisfied first.” Per IDAPA Code 37.03.08 Water Appropriation Rules, IDWR relies on protestants to “bear the initial burden of coming forward with evidence for those factors relevant to [the public interest criteria described in]...Section 42-203A(5), Idaho Code....” Although the SDEIS notes that Perpetua submitted additional water right applications for permit in December 2021, the SDEIS fails to disclose that several administrative protests concerning negative impacts to the public interest criteria have been filed with IDWR. The Tribe asks that the number and nature of protests filed with IDWR regarding Perpetua’s pending water rights be formally added to the record. The Forest should not proceed with an FEIS while the necessary water right applications (and numerous other environmental permits) are pending.</p>	WTR	<p>Protests filed with IDWR and their resolution is outside the scope of the EIS as they are part of an independent permitting process managed by IDWR.</p>

Samuel Penney (Chairman)	19396	87	<p>3.9 Surface Water and Groundwater Quality</p> <p>The SDEIS states that “[t]he IDEQ is responsible for coordinating and administering groundwater and surface water downgradient of the mining activity must meet the water quality standards? quality protection programs in the state of Idaho. IDEQ also is responsible for establishing a point of compliance location, if applied for by a mine operator and pursuant to the Idaho Ground Water Quality Rule... where groundwater and surface water downgradient of mining activity must meet established water quality standards. If a point of compliance is not applied for, the mine operator must meet the ground water quality standards in ground water both within and beyond the mining area.” Where are the locations where groundwater and surface water downgradient of the mining activity must meet the water quality standards?</p>	WTR	<p>The locations where groundwater and surface water downgradient of the mining activity must meet water quality standards would be determined by IDEQ as part of its permitting processes.</p> <p>The EIS examines predicted groundwater and surface water chemistry compared to existing conditions and water quality standards at a number of locations as described in SDEIS 4.9.2.2. That examination describes potential Project impacts to groundwater and surface water quality and develops mitigation measures for those effects but does not establish points of compliance which are within IDEQ's purview.</p>
Samuel Penney (Chairman)	19396	88	<p>Table 3.9-6a shows more analytes with exceedances than are mentioned in the text. In addition, there are several analytes with the non-detect levels greater than the Strictest Potentially Applicable Standards (ex. Cd, Cu, Pb). Please acknowledge these and discuss any ramifications.</p>	WTR	<p>The text has been revised to note constituents from Table 3.9-6a with concentrations greater than standards and acknowledges the limitations of non-detect levels.</p>
Samuel Penney (Chairman)	19396	89	<p>Section 3.9.4.2, Tailings Decant Solution Chemistry subsection, page 3-158.</p> <p>Only five samples of synthetic tailings materials appear to have been analyzed. Based on Table 3.9-7 results are shown for samples from five different areas. Does this mean only one sample per area was analyzed? This does not seem to be a sufficient number to fully characterize the decant solution, as results would feed into the water treatment plant design and groundwater chemistry under the TSF.</p>	WTR	<p>There would be five types of ore mined and processed during the Project lifetime, and hence, would produce tailings with decant solution. The number of samples is based on the number of ore types present. Most constituents analyzed are present in the decant solution chemistry at concentrations greater than water quality standards making the results informative for water treatment plant designs which need to account for a variety of analytes and analyte concentrations.</p>
Samuel Penney (Chairman)	19396	90	<p>Section 3.9.4.2, Humidity Cell Test Results subsection, page 3-166.</p> <ul style="list-style-type: none"> • Explain the purpose of this test. What are the Phase 1 and Phase 2 HCT cells? • The SDEIS on page 3-166 and Table 3.9-8 have some conflicting information. The table lists other constituents that exceed the strictest potentially applicable water quality criteria that are not mentioned in the text or incorrectly listed as not exceeding (e.g., Pb, Ni, Se, Ag, Th, F). Were all the data used for all the analytes when modeling source terms? 	WTR	<p>Humidity cell tests are laboratory tests designed to simulate oxidation reactions and metal leaching from mined materials. An initial phase of tests (Phase 1) was conducted based on the understanding of the distribution of rock types in mined materials at the conception of the testing plan. Phase 2 was added to supplement the Phase 1 testing to provide additional information on rock types present in the mine design but not tested as part of Phase 1.</p> <p>The text has been revised for consistency.</p> <p>SDEIS Section 4.9.1.1 describes the development of source terms from the humidity cell test data. In brief, all the tests were utilized to develop source terms based on their steady-state leachate results. The implications for excluding first-flush humidity cell leachate data are described in SDEIS Section 4.9.2.4.</p>
Samuel Penney (Chairman)	19396	91	<p>In the SDEIS, copper analysis criteria was derived using the Biotic Ligand Model per guidance contained in IDEQ's Implementation Guidance for the Idaho Copper Criteria for Aquatic Life (2017). A conservative chronic copper analysis criteria was estimated by applying the lowest of the 10th percentile chronic criteria based on regional classifications for the Salmon River basin, Idaho Batholith, and third order streams, which led to an applied acute criterion of 2.4 µg/L.</p> <p>However, the SDEIS should have also applied the site class + river/stream metric, where rivers are defined as any water with stream order 2:5 and streams are defined as any water with stream order <5. Using that metric, the conservative acute and chronic copper criteria estimates would be 1.0 and 0.6 µg/L, respectively, based on a Mountain Stream site class designation.</p>	WTR	<p>SDEIS Table 3.9-1 provides the rationale for standards used for water chemistry comparison in the water quality analysis. These values represent the currently adopted regulatory criteria for comparison at the time of the SDEIS publication.</p>
Samuel Penney (Chairman)	19396	92	<p>The SDEIS relies on an arsenic water quality criterion of 10 µg/L. In September of 2016, EPA disapproved Idaho's human health criteria of 10 µg/L for both consumption of fish only and consumption of fish and water. EPA entered into a consent decree with Northwest Environmental Advocates that requires EPA to either approve of a new criterion submission by Idaho or to propose and finalize federal criteria for Idaho in the absence of EPA approval of a criterion adopted by Idaho. It is not appropriate to use a disapproved criterion for this assessment that has since been extended twice by Idaho for a period of six years and has yet to be approved of by EPA. Instead, the SDEIS should utilize EPA's National Recommended Water Quality Criteria for Human Health for the consumption of Water + Organism of 0.018 µg/L.</p>	WTR	<p>SDEIS Table 3.9-1 provides the rationale for standards used for water chemistry comparison in the water quality analysis. These values represent the currently adopted regulatory criteria for comparison at the time of the SDEIS publication.</p>

Samuel Penney (Chairman)	19396	93	The SDEIS lists Aluminum as a constituent of concern. There are no promulgated standards for Aluminum in Idaho, and in the absence of a state water quality standard, the authors of the SDEIS refer to the an analysis criterion for Aluminum of 0.38 mg/L, based on the EPA "Recommended Aquatic Life Criteria". Rather than a static number, EPA's Recommended Aquatic Life Criteria for Aluminum in Freshwater for the Protection of Aquatic Life is dependent upon the water chemistry parameters found at a particular site. These criteria use Multiple Linear Regression ("MLR") models to normalize the toxicity data and provide a range of acceptable values. The criteria are calculated based on a site's pH, total hardness, and DOC. The EPA has a tool called the Aluminum Criteria Calculator that should be used to determine both acute and chronic criteria for sites throughout the Stibnite project area. It is unclear if this methodology is being used to determine the analysis criteria. Regardless, the strictest applicable surface water quality standard (0.05 mg/L) should be used as the analysis criterion.	WTR	SDEIS Table 3.9-1 provides the rationale for standards used for water chemistry comparison in the water quality analysis. These values represent the currently adopted regulatory criteria for comparison at the time of the SDEIS publication.
Samuel Penney (Chairman)	19396	94	The SDEIS uses 0.0015 mg/L as the strictest standard to be applied for selenium,166 and cites EPA's Freshwater Aquatic Life Criteria. However, 0.0015 mg/L is only the chronic criterion for lentic waters. EPA recommends a multi-media criterion consisting of four elements, two of which are based on the concentration of selenium in fish tissue (eggs and ovaries, and whole-body or muscle) and two elements are based on the concentration of selenium in the water-column (two 30-day chronic values and an intermittent value). EPA recommends that when implementing the criterion, the fish tissue elements take precedence over the water column elements.	WTR	SDEIS Table 3.9-1 provides the rationale for standards used for water chemistry comparison in the water quality analysis. These values represent the currently adopted regulatory criteria for comparison at the time of the SDEIS publication.
Samuel Penney (Chairman)	19396	95	The SDEIS uses EPA's Drinking Water MCL of 2,000 µg/L for the analysis of barium. Instead, the SDEIS should utilize EPA's National Recommended Water Quality Criteria for Human Health for the consumption of Water + Organism of 1,000 µg/L.	WTR	SDEIS Table 3.9-1 provides the rationale for standards used for water chemistry comparison in the water quality analysis. These values represent the currently adopted regulatory criteria for comparison at the time of the SDEIS publication.
Samuel Penney (Chairman)	19396	96	The SDEIS uses the narrative, "No numeric human health standard has been established for beryllium. However, permit authorities will address beryllium in NPDES permit actions using the narrative criteria for toxics in Section 200 of IDAPA 58.01.02, which states: Surface waters of the state shall be free from toxic substances in concentrations that impair designated beneficial uses. These substances do not include suspended sediment produced as a result of nonpoint source activities." Instead, the SDEIS should utilize EPA's Drinking Water MCL of 4 µg/L as the surface water quality standard for beryllium.	WTR	SDEIS Table 3.9-1 provides the rationale for standards used for water chemistry comparison in the water quality analysis. These values represent the currently adopted regulatory criteria for comparison at the time of the SDEIS publication.
Samuel Penney (Chairman)	19396	97	The SDEIS uses IDAPA 58.01.02 - CCC (chronic) criterion for the analysis of cadmium. This calculated criterion is dependent upon hardness and is appropriate to use so long as the criterion is less than EPA's Drinking Water MCL of 5 µg/L. If the calculated criterion for a data point exceeds 5 µg/L, then EPA's Drinking Water MCL for cadmium becomes the most stringent criterion and should be used for analysis.	WTR	SDEIS Table 3.9-1 provides the rationale for standards used for water chemistry comparison in the water quality analysis. These values represent the currently adopted regulatory criteria for comparison at the time of the SDEIS publication.
Samuel Penney (Chairman)	19396	98	The SDEIS uses the IDAPA 58.01.02 - CCC (chronic) criterion for the analysis of lead. This calculated criterion is dependent upon hardness and is appropriate to use so long as the criterion is less than EPA's Drinking Water MCL of 15 µg/L. If the calculated criterion for a data point exceeds 15 µg/L, then EPA's Drinking Water MCL for lead becomes the most stringent criterion and should be used for analysis.	WTR	SDEIS Table 3.9-1 provides the rationale for standards used for water chemistry comparison in the water quality analysis. These values represent the currently adopted regulatory criteria for comparison at the time of the SDEIS publication.
Samuel Penney (Chairman)	19396	99	The SDEIS uses the IDAPA 58.01.02 - CCC (chronic) criterion for the analysis of nickel. This calculated criterion is dependent upon hardness and is appropriate to use so long as the criterion is less than EPA's Drinking Water MCL of 58 µg/L. If the calculated criterion for a data point exceeds 58 µg/L, the EPA' s Drinking Water MCL for nickel becomes the most stringent criterion and should be used for analysis.	WTR	SDEIS Table 3.9-1 provides the rationale for standards used for water chemistry comparison in the water quality analysis. These values represent the currently adopted regulatory criteria for comparison at the time of the SDEIS publication.
Samuel Penney (Chairman)	19396	100	The SDEIS uses the IDAPA 58.01.02 criterion range of 6.5-9.0 for the analysis of pH. Instead, the SDEIS should utilize EPA's Secondary Drinking Water Standard of 6.5-8.5 µg/L.	WTR	SDEIS Table 3.9-1 provides the rationale for standards used for water chemistry comparison in the water quality analysis. These values represent the currently adopted regulatory criteria for comparison at the time of the SDEIS publication.
Samuel Penney (Chairman)	19396	101	The SDEIS uses the IDAPA 58.01.02 - CMC (acute) criterion for the analysis of silver. This calculated criterion is dependent upon hardness and is appropriate to use so long as the criterion is less than EPA's National Recommended Water Quality Criteria for Aquatic Life - CMC (acute) of 3.2 µg/L. If the calculated criterion for a data point exceeds 3.2 µg/L, then EPA's National Recommended Water Quality	WTR	SDEIS Table 3.9-1 provides the rationale for standards used for water chemistry comparison in the water quality analysis. These values represent the currently adopted regulatory criteria for comparison at the time of the SDEIS publication.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			Criteria for Aquatic Life - CMC (acute) for silver becomes the most stringent criterion and should be used for analysis.		
Samuel Penney (Chairman)	19396	102	The SDEIS uses the IDAPA 58.01.02 - CCC (chronic) criterion for the analysis of zinc. This calculated criterion is dependent upon hardness and is appropriate to use so long as the criterion is less than EPA's National Recommended Water Quality Criteria for Aquatic Life of 120 µg/L. If the calculated criterion for a data point exceeds 120 µg/L, then EPA's National Recommended Water Quality Criteria for Aquatic Life for zinc becomes the most stringent criterion and should be used for analysis.	WTR	SDEIS Table 3.9-1 provides the rationale for standards used for water chemistry comparison in the water quality analysis. These values represent the currently adopted regulatory criteria for comparison at the time of the SDEIS publication.
Samuel Penney (Chairman)	19396	103	Mercury. While water column methylmercury concentration predictions are important to elucidate the long-term impacts of the proposed mining at the site, the applicable water quality standard applies only to fish tissue on the basis of human consumption. Many tribal members continue to exercise their treaty reserved rights to fish for salmon and steelhead in the EFSFSR downstream of the proposed mine site. In order to ensure the proposed action will not negatively affect tribal health or impact tribal treaty rights in the EFSFSR, fish tissue samples need to be analyzed throughout the site and the potential tribal health impacts need to be addressed in the SDEIS.	WTR	The migratory nature of fish in the system makes fish tissue monitoring indeterminate as to the source of constituents identified in fish tissue. Therefore, monitoring on benthic invertebrates would be the preferred monitoring approach.
Samuel Penney (Chairman)	19396	104	Methylmercury impacts have been detected hundreds of miles downstream of mine point sources. Treaty-reserved rights to fish at usual and accustomed places are already impacted by methylmercury issues in the Snake River downstream of the Hells Canyon Complex, leading to the proposed Total Maximum Daily Load for Hg currently being negotiated between Idaho, Oregon, and EPA. Due to bioaccumulation of mercury, sturgeon harvest advisories from the Tribe's Fishery Commission have been in place since 2015 for sturgeon over three feet total length. Any increase in total mercury discharge from the Project may result in increased methylmercury concentrations in the mainstem Salmon and Snake Rivers, and would continue to threaten tribal members ability to harvest and consume sturgeon within the 1967 Indian Claims Commission aboriginal territory for the Nez Perce Tribe.	WTR	Predicted total mercury concentrations in surface waters are described in SDEIS Tables 4.9-18 through 4.9-21. Predicted concentrations are comparable to existing site conditions and below surface water quality criteria. Site methylmercury concentrations are also estimated based on conservative estimates for methylation rates on-site. The Project is not expected to affect methylation rates downstream, and those rates have not been quantified as part of the EIS analysis scope. However, methylation rates in the Salmon River watershed, typically between 0.37 and 1 percent (Fleck et al. 2017), are not expected to be modified by Project effects (see Section 4.9.2.2).
Samuel Penney (Chairman)	19396	105	The SDEIS fails to address potential nitrogen contamination resulting from the proposed actions. Potential sources of nitrogen components in the proposed actions include leftover residues from explosives, precipitate from cyanide ore processing, domestic wastewater effluent, and increased sediment pollution. Since all these potential sources are included in the proposed Project, the following nitrogen components should be addressed specifically in the SDEIS and in the Sanitary Wastewater Individual Permit Application. The Sanitary Wastewater Idaho Pollutant Discharge Elimination System Program ("IPDES") permit or permit application has yet to be shared for review.	WTR	SDEIS Section 4.9.2.2 describes predicted nitrate and ammonia concentrations resulting from the Project. The IPDES permit for wastewater discharge is still under consideration by IDEQ. The EIS analysis is based on operation of a wastewater treatment under IPDES program requirements on discharges.
Samuel Penney (Chairman)	19396	106	Ammonia is highly toxic to aquatic organisms, particularly to salmonids and mussels. In high enough concentrations, ammonia can build up in the internal tissues and blood of aquatic organisms, often leading to death. Ammonia can also absorb to several metal ions and be deposited into sediments which can be toxic to benthic or surface aquatic biota. Potential sources of ammonia in the proposed action include residue from Ammonium Nitrate Fuel Oil, residual cyanide from the cyanide neutralization facility where oxidized cyanide forms carbonate and ammonia, and waste effluent from the housing facility. Water quality criteria have been established by EPA and are dependent upon pH and water temperature. Individual criteria should be calculated for each data point collected at each monitoring location. Due to its close association with mining operations and its high toxicity, especially to salmonids, current conditions must be characterized and the potential impacts should be included in the SDEIS. Ammonia criteria should also be addressed in the Sanitary Wastewater IPDES permit that has yet to be shared for review. The ammonia water quality standard value of 2.1 mg/L is not explained in the SDEIS nor is it the strictest potentially applied water quality standard.	WTR	SDEIS Section 4.9.1.5 describes the predicted ammonia concentrations associated with the Project. The 2.1 mg/l standard is based on the Idaho Surface Water Criteria for Cold Water Biota for chronic exposure using the pH and temperature-dependent calculation found at Http://www.deq.idaho.gov/water-quality/surface-water/water-quality-criteria/ .
Samuel Penney (Chairman)	19396	107	Nitrate is relatively harmless in drinking water at low concentrations, but can contribute to eutrophication in streams and rivers. However, nitrate can go through partial denitrification by bacteria to form the less stable and more toxic nitrite ion. In addition, no surface water quality criterion was	WTR	Conditions for eutrophication and reduction from nitrate to nitrite are not anticipated under predicted site conditions.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>assigned for nitrate+nitrite but the SDEIS uses the groundwater quality standard value of 10 mg/L for the surface water assessment and the Target Post-Water Treatment Plant Effluent Analyte Treatment Objective standard. EPA established ambient water quality criteria recommendations for nitrate+nitrite in the western forested mountains guidance (Ecoregion II, Level III ecoregion 15). The guidance recommends a nitrate+nitrite water quality criterion of 0.02 mg/L. However, detection limits reported for nitrate+nitrite in the Surface Water Quality Baseline Study were 0.05 mg/L, which is higher than the recommended water quality criterion so additional data should be collected at the site and analyzed with a lower detection limit in order to accurately characterize current site conditions.</p> <p>Total Kjeldahl nitrogen is the sum of organic nitrogen and ammonia nitrogen and is often monitored in wastewater effluent and its receiving body. Kjeldahl nitrogen was monitored in the current conditions analysis but was not included in the site-wide water chemistry modeling report. In addition, no water quality criterion was assigned for Kjeldahl nitrogen in the Surface Water Quality Baseline Study; EPA established ambient water quality criteria recommendations for Kjeldahl nitrogen in the western forested mountains guidance (Ecoregion II, Level III ecoregion 15). The guidance recommends a Kjeldahl nitrogen water quality criterion of 0.08 mg/L. Since potential sources of Kjeldahl nitrogen are included in the proposed action, Kjeldahl nitrogen should be reanalyzed against this criterion and included in the SDEIS and IPDES permits, or supporting documents.</p>		<p>There are no adopted nitrate+nitrite standards aside from the drinking water criteria. There are also no adopted standards for Total Kjeldahl nitrogen.</p> <p>The SDEIS Section 4.9.2.2 describes the predicted nitrogen compounds associated with Project activities (i.e., nitrate and ammonia).</p>
Samuel Penney (Chairman)	19396	108	<p>Total nitrogen is the sum of Kjeldahl nitrogen and nitrate+nitrite and is often monitored in wastewater effluent and its receiving body, and is often also correlated with sediment erosion.</p> <p>Total nitrogen was monitored in the current conditions analysis but was not included in the sitewide water chemistry modeling report. Why was it omitted? Also, no water quality criterion was assigned for total nitrogen in the Surface Water Quality Baseline Study; EPA established ambient water quality criteria recommendations for total nitrogen in the western forested mountains guidance (Ecoregion II, Level III ecoregion 15). The guidance recommends a total nitrogen water quality criterion of 0.20 mg/L. Since potential sources of total nitrogen are included in the proposed action, it should be reanalyzed against this criterion and included in the SDEIS and IPDES permits, or supporting documents.</p>	WTR	<p>There are no adopted nitrate+nitrite standards aside from the drinking water criteria. There are also no adopted standards for Total Kjeldahl nitrogen.</p> <p>The SDEIS Section 4.9.2.2 describes the predicted nitrogen compounds associated with Project activities (i.e., nitrate and ammonia). Monitoring requirements associated with total nitrogen could be applied as part of IDEQ's IPDES permit, but the nitrogen compounds related to proposed activities have been included in the SDEIS.</p>
Samuel Penney (Chairman)	19396	109	<p>Phosphorus is relatively harmless in drinking water at low concentrations, but can contribute to eutrophication in streams and rivers. Sources of phosphorus include human or animal waste, detergents, food waste, and sediment erosion. While both total and dissolved phosphorus concentrations were included in the current conditions monitoring, only dissolved phosphorus was included in the current conditions and predictive modeling. Why was total phosphorus omitted?</p> <p>Total phosphorus is highly correlated with sediment and should have been included in the sitewide water chemistry analysis. In addition, no water quality criterion was assigned for total phosphorus in the Surface Water Quality Baseline Study; EPA established ambient water quality criteria recommendations for total phosphorus in the western forested mountains guidance (Ecoregion II, Level III ecoregion 15). The guidance recommends a total phosphorus water quality criterion of 7.75 µg/L. Since potential sources of phosphorus are included in the proposed action, it should be reanalyzed against this criterion and included in the SDEIS and IPDES permits or supporting documents.</p>	WTR	<p>Conditions for eutrophication are not anticipated under predicted site conditions.</p> <p>Phosphorus concentrations in baseline surface water were typically below analytical method detection limits. Likewise, they were seldom detected in the geochemical testing of mined materials. Therefore, predicted phosphorus concentrations in surface water do not vary from existing conditions as presented in SDEIS Tables 4.9-18 through 4.9-21.</p>
Samuel Penney (Chairman)	19396	110	<p>Since the publication of many of the proposed project's technical reports, several federal and state water quality standards have been changed. The following is a summary of constituents that need to be reanalyzed to reflect the most current and strictest potentially applicable standards: (TABLE)</p>	WTR	<p>SDEIS Table 3.9-1 provides the rationale for standards used for water chemistry comparison in the water quality analysis. These values represent the currently adopted regulatory criteria for comparison at the time of the SDEIS publication.</p>
Samuel Penney (Chairman)	19396	111	<p>The SDEIS and its supporting documents provide abundant evidence that the SGP has been heavily influenced by historic mining. Under the Idaho Ground Water Quality rules, the natural background level is defined as “[t]he level of any constituent in the groundwater...unaffected by human activities.” Historic mining legacy impacts make it difficult to establish baseline conditions for water quality comparisons. As stated in the Water Resources Summary Report, “[t]he areas with little or no historical mining...on the west side of the District such as the Fiddle and North prospects, may provide opportunities to establish natural background water quality in seeps and springs or groundwater monitoring wells.” A hydrology field survey completed in November of 2012 shows fairly significant</p>	WTR	<p>Existing water quality conditions were utilized as a basis of comparison for predicted water quality conditions associated with Project effects. The Project is not expected to affect water quality in seeps and springs in the headwaters of drainages above the Project location. Therefore, water chemistry observations from these locations were not utilized as part of the basis of comparison for Project effects.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>(>5 gallons per minute) springs and seeps located in and that provide flow to the headwaters of perennial and intermittent drainages including Hennessey Creek, Fiddle Creek, Meadow Creek, East Fork Meadow Creek (Blowout Creek), Garnet Creek, Midnight Creek, West End Creek, and the EFSFSR. In low flow conditions, it is surmised that springs and seeps sustain flows within these streams in the absence of precipitation.</p> <p>Although water quality samples “were collected for analytes that could be of interest to one or more agencies [involved in the permitting process with respect to surface water quality regulations]”, baseline water quality testing performed on the seeps and springs in the headwaters of various streams within the Project area were not tested for constituents of concern including metals like arsenic and antimony. A more accurate picture of how the SGP will influence water quality may have been generated if these seeps and springs, particularly those with no legacy mining impacts in the headwaters of Fiddle Creek, had been tested and included as baseline water quality conditions rather than conditions at already degraded stream sampling sites.</p>		
Samuel Penney (Chairman)	19396	186	<p>4.8 Surface Water and Groundwater Quantity</p> <p>Section 4.8 of the SDEIS defines the environmental consequences of the proposed action to surface water and groundwater quantity. Throughout the SDEIS, the Forest Service highlights the interplay between seasonal surface precipitation (i.e., snow accumulation, melt, and runoff), streamflows, groundwater expressions as springs and seeps at the surface, and groundwater flows. Given the complexities of this interconnected hydrology, the Tribe is concerned that the SDEIS is grievously underestimating the impacts to surface flows, groundwater levels, and groundwater dependent ecosystems.</p>	WTR	<p>SDEIS Section 4.8.2.2 describes predicted effects on surface water flows, groundwater levels, and groundwater dependent ecosystems. Reductions in stream flow are presented in Figures 4.8-11 through 4.8-17 with groundwater drawdown depicted in Figure 4.8-9 and its relationship to groundwater dependent ecosystems presented in Figure 4.8-10.</p> <p>As presented, these effects occur through much of the analysis area.</p>
Samuel Penney (Chairman)	19396	187	<p>For surface flows, the SDEIS correctly notes that the Idaho Water Resource Board holds two minimum flow water rights located downstream of the proposed project area: #77-14190 for the EFSFSR and #77-14174 for the SFSR.370 The SDEIS fails to include minimum flow water right #77-14193 on Sugar Creek.</p>	WTR	<p>The minimum flow rights on Sugar Creek has been added to the description of minimum flow water rights in the EIS.</p>
Samuel Penney (Chairman)	19396	188	<p>Additionally, it is unclear how alterations within the West End drainage - specifically, the stream diversion and the creation of the West End pit lake - will impact flows within Sugar Creek. The SDEIS states that the minimum flow water rights are subordinate to future Domestic, Commercial, Municipal, and Industrial (“DCMI”) uses and, in some cases, future non-DCMI allotments. The Forest Service, however, fails to provide important context. Although Idaho’s minimum flow protections for streams are woefully inadequate, the primary goal of the settlement agreement provisions detailed in the 2004 Snake River Water Rights Agreement were “to conserve and enhance fish habitat in order to address ESA concerns.” As a result, minimum stream flow water rights were established in streams within the Clearwater and Salmon River Basins that, according to the State of Idaho’s water management plan, “provide significant protection for steelhead, salmon, and bull trout.” Furthermore, IDWR has a responsibility to “regulate the delivery of the instream flows through the designated stream reaches.” The Tribe wonders how this can be achieved when, to date, it is unknown whether the EFSFSR, the SFSR, or Sugar Creek are meeting minimum stream flows.</p>	WTR	<p>As described in Section 4.8.2.2, Table 4.8-4, and Figure 4.8-15, Project effects on Sugar Creek flows are predicted to be minimal, less than 3 percent of monthly flows.</p>
Samuel Penney (Chairman)	19396	190	<p>For groundwater levels, the hydrologic model appears to consider the water table as a static parameter that remains constant despite pumping, capture of runoff/contact water, and changes in groundwater loss/recharge due to stream diversions. It seems reasonable that stream diversions and capture of runoff may alter the water table in such a way that negatively impacts groundwater recharge. Furthermore, the SDEIS notes that “[c]limate change impacts to groundwater could decrease the availability of groundwater...in the area...[and that] [c]limate change induced changes in precipitation and evaporation could also impact the overall site-wide water balance which could result in significant changes to the amount of water being treated and discharged.”</p> <p>This statement, followed by a lack of meaningful discussion on how climate change induced changes could impact the site-wide water balance, highlight the inadequacy of the Forest Service’s reliance on water rights permitting requirements to protect water quantity.</p>	WTR	<p>The SDEIS accounts for changes in groundwater levels as depicted in Figure 4.8-9. These changes include the effects of groundwater pumping and loss of recharge associated with stream diversion.</p> <p>Quantitative description of potential climate change effects on precipitation and evaporation is outside the scope of the EIS analysis. Qualitative descriptions of the potential effects of climate change on the affected environment are included in SDEIS Section 4.4.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Samuel Penney (Chairman)	19396	191	The SDEIS states, “Instream rights on the SFSR are subordinate to 20.6 cubic feet per second (“cfs”); maximum diversions proposed by Perpetua from all sources and uses would be 9.68 cfs, within the allowance of the SFSR instream rights.” Where did 20.6 come from? Please provide additional information to clarify. Related, it poses an important question on whether a single applicant can command nearly half of the legally appropriable water in the stream. A recent legal review of Idaho case law found that “[c]ases involving surface water consistently have held that an appropriator may not command the entire flow of a stream to effect an appropriation of only a portion.”	WTR	The SDEIS describes the existing water rights and the predicted Project effects associated with those water rights. The subordination of water rights is described in Water Right 77-14174. Appropriation of water rights in a stream is the purview of IDWR.
Samuel Penney (Chairman)	19396	193	<ul style="list-style-type: none"> Flows from springs and seeps are expected to be reduced in the areas where groundwater levels are lowered. This impacts the associated vegetation and ecosystems, etc. 	WTR	Comment noted. This is consistent with the impact assessment as presented in SDEIS Section 4.8.2.2.
Samuel Penney (Chairman)	19396	194	<ul style="list-style-type: none"> Reductions are expected in stream flows, particularly in baseflow in certain mining years for certain streams/reaches. These could cause flows less than the minimum stream flows if IDWR approves the water right application. 	WTR	Stream flow reductions are expected to occur due to effects of the Project. However, flows less than minimum stream flows are not expected and further, would not be authorized by IDWR under its water rights approval.
Samuel Penney (Chairman)	19396	195	<ul style="list-style-type: none"> What are the impacts in Mine Year-1 from filling the TSF? This doesn’t appear to have been modeled. Please provide additional details. 	WTR	Effects of Project water usage on stream flows are depicted starting in Year -2 in Figures 4.8-11 through 4.8-17. Discharge of tailings solution to the Tailings Storage Facility would start in Year -1 as depicted in SDEIS Figure 2.4-10 and Figure 4.8-3 and has been included in the analysis.
Samuel Penney (Chairman)	19396	196	<ul style="list-style-type: none"> Is there enforcement for minimum stream flow diversions? Where are there locations that surface water flows need to be met? 	WTR	The locations for minimum stream flows are described in SDEIS Section 3.9.4.4. Enforcement of minimum stream flows is within the purview of IDWR.
Samuel Penney (Chairman)	19396	199	Based on the predicted surface water chemistry, elevated concentrations of arsenic, antimony, mercury, and residual cyanide will be present and subsequently leaching at increasing rates during this time frame. Compared to the entire water storage capacity (maximum of one foot of hydraulic head allowed to persist above tailings) of the TSF this volume is relatively small, but still remains an entirely unacceptable amount of contaminated water entering the watershed. The underdrain is designed to collect much of this seepage water but according to the SDEIS “[w]aters infiltrating into the subsurface under the mine facilities would mix with alluvial groundwater and are not subject to water treatment except in instances where alluvial groundwater is subsequently pumped for mine dewatering.”	WTR	Comment noted. This is consistent with the impact assessment as presented in SDEIS Section 4.8.2.2.
Samuel Penney (Chairman)	19396	204	The SDEIS states ammonia concentrations were not explicitly modeled. An explanation is provided in the Water Quality Specialist Report in Section 5.2.5. The SDEIS should provide the reasoning in this report.	WTR	The ammonia explanation from the Specialist Report has been included in the SDEIS.
Samuel Penney (Chairman)	19396	205	Figure 4.9-3 shows a large spike in TSF Buttress seepage volume to the alluvial aquifer during the year of cover placement. Please explain why. Also, if the cover is placed, why are the alluvial recharge volumes similar to or higher than before the cover?	WTR	The volume of predicted TSF Buttress seepage with the potential to recharge alluvium is based on an estimate of preferential flow of meteoric water through the buttress material. The amount of meteoric water incident on the buttress reaches a maximum at full facility buildout prior to the installation of a geosynthetic liner over the buttress which would subsequently reduce the volume of meteoric water contacting the buttress material.
Samuel Penney (Chairman)	19396	206	Tables 4.9-2 and -3 show concentrations of constituents that exceed the strictest potentially applicable surface water quality criteria from runoff and seepage from the TSF Buttress and Embankment, respectively. The SDEIS states toe seepage and runoff go to the contact water pond that is treated. However, some of the water infiltrates into the aquifer. They discuss the modeled results of mixing this water with groundwater, which shows antimony and arsenic above the water quality standards during operations and post cover (Table 4.9-4). To prevent the degradation of groundwater, why isn’t there a liner under the embankment and buttress?	WTR	SDEIS Figures 3.9-20 and 3.9-21 illustrate baseline arsenic and antimony concentrations in groundwater beneath the TSF buttress. Under existing conditions, groundwater concentrations exceed antimony and arsenic water quality criteria. SDEIS Table 4.9-4 presents the predicted groundwater concentrations below the TSF Embankment and Buttress. These concentrations vary little from existing conditions during operations, increase during closure activities as covers are placed on the facility, then decrease to near existing conditions thereafter. Therefore, use of a liner under the TSF Embankment and Buttress would have limited effect on groundwater antimony and arsenic concentrations.
Samuel Penney (Chairman)	19396	207	Water Treatment New Source Performance Standard on page 8-2 of the 20220131 Water Management Plan for Stibnite states, “In addition to the Idaho surface water standards, the SGP is also subject to the ELGs as codified in the New Source Performance Standards for gold mines in 40 CFR 440.104.	WTR	The EIS has been revised to include the treatment target for copper. Water treatment designs target reductions in constituents in the feed water that are above water quality criteria. To address TSS in feed water, water treatment processes include clarification and filtration steps as part of their processing to remove solids from the treated water so that the chemical water treatment is effective. Therefore, the water treatment designs

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			The parameters with ELGs are pH, total suspended solids, cadmium, copper, lead, mercury, and zinc.” The target post-water treatment plant effluent analyte concentrations in Table 4.9-10 do not include copper or TSS. Would the WTP design be able to meet these standards? In addition, these parameters should be included in all appropriate surface water monitoring locations.		do not include a criteria for TSS in their discharge. However, the discharge would be subject to monitoring and permit thresholds for TSS for compliance with IPDES permits.
Samuel Penney (Chairman)	19396	208	The SDEIS states after closure and a liner on the TSF, the water treatment plant solids would go on top of the liner. Please describe the water cycle associated with this (ex. water capture and treatment).	WTR	Water treatment residuals generated from the water treatment plant following placement of the TSF liner would be located in an 8.5-acre area near the northeast corner of the TSF. Berms or cofferdams would be used to contain the residuals along with a temporary cover to minimize contact of the residuals with meteoric water. Following cessation of water treatment, a permanent geosynthetic cover would be applied over the residuals then growth material would be placed over the geosynthetic cover and revegetated. Residual water collected from the TSF would be conveyed to the closure water treatment plant located on the TSF buttress. The treatment process for the collected water is described in SDEIS Figure 4.9-12 which would discharge the treated water to Meadow Creek.
Samuel Penney (Chairman)	19396	209	West End Pit Lake Chemistry The SDEIS predicts post closure exceedances of water quality standards for dissolved antimony, arsenic, and mercury (the table also shows lead in some years). The only outflows appear to be groundwater. In the Groundwater Chemistry section, it says if groundwater is below water quality standards this may raise concentrations, but if they are above the standards then the new concentrations result in little change. This information is vague. How does the lake chemistry impact groundwater concentrations?	WTR	Existing groundwater arsenic and antimony concentrations in the West End Pit area are characterized via monitoring well MWH-B20 which exhibits concentrations above water quality standards (see SDEIS Figures 3.9-20 and 3.9-21). Based on comparison to water quality data from MWH-B20, pit lake outflows would not affect local groundwater concentrations relative to water quality criteria. While mercury concentrations in the West End Pit lake are predicted to be above surface water criteria, they are below groundwater criteria. Existing groundwater mercury concentrations in the West End pit area are also below groundwater criteria and pit outflow to groundwater would not affect those concentrations relative to the groundwater criteria.
Samuel Penney (Chairman)	19396	210	Midnight Backfill Porewater chemistry exceeds the water quality standards for antimony, arsenic, manganese, lead, sulfate, and TDS. How does this impact groundwater quality beneath the pit?	WTR	The Midnight pit backfill is above the level of local groundwater. Reclamation and closure of the backfilled pit would involve grading of the surface to promote drainage away from the backfill plus growth media placement and revegetation. These closure steps would inhibit movement of pore water from the backfill to groundwater.
Samuel Penney (Chairman)	19396	211	Although the SDEIS states the backfill would be mounded at closure to promote runoff, why isn't a cover proposed over the Midnight backfill?	WTR	The regrading, growth media placement, and revegetation are anticipated to be sufficient to retain pore water in the unsaturated Midnight Pit backfill and limit migration to the water table.
Samuel Penney (Chairman)	19396	212	Section 4.9.2.2, Yellow Pine and Hanger Flats Backfill subsection: Water chemistry in the inundated backfill within these pits is expected to have antimony and arsenic concentrations above groundwater quality standards, and elevated concentrations of mercury that are below groundwater standards but may contribute water quality standard exceedances in surface water. The SDEIS does not provide information on when these exceedances occurred, but Tables 4.9-14 and 4.9-15 show concentration exceedances post closure. How does this affect groundwater concentrations beneath these pits?	WTR	Inundation of backfill in the Hangar Flats and Yellow Pine pits would occur post-closure when groundwater drawdown by dewatering recovers to elevations above the pit bottoms. As described in SDEIS Section 4.9.2.2, interaction between the backfill material and groundwater would result in groundwater antimony and arsenic concentrations above groundwater quality criteria within the backfill. In many instances, this would occur in groundwater where antimony and arsenic concentrations are already above water quality criteria in their existing condition.
Samuel Penney (Chairman)	19396	213	Figure 4.9-15. The points (locations) at which water quality predictions are made are missing from the Yellow Pine and Hanger Flats pit drawings. Also, there is no water table shown on the Yellow Pine pit figure. Please add.	WTR	Predicted pit backfill pore water chemistry is developed for the entirety of the backfill based on an aggregation of the materials placed as backfill. The components of that aggregated composition are described in SDEIS Figure 4.9-16. The recovered groundwater level in the Yellow Pine pit has been added to Figure 4.9-15.
Samuel Penney (Chairman)	19396	214	Section 4.9.2.2, Groundwater Chemistry subsection: Midnight pit backfill, A groundwater discharge location to surface water isn't mentioned. Please include a discussion.	WTR	Groundwater discharges from the West End area (including the Midnight pit area) to surface waters are depicted in the bottom portion of Figure 4.9-20.
Samuel Penney (Chairman)	19396	215	The SDEIS states, “Existing groundwater monitoring data near the confluence of Meadow Creek and the East Fork SFSR exhibit antimony and arsenic concentrations above groundwater standards, indicating the mixture of leachate with these waters would result in little change to groundwater concentrations relative to standards. This is also the case for groundwater concentrations with the Sugar Creek	WTR	Comment noted. This is consistent with the impact assessment as presented in SDEIS Section 4.9.2.2.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			drainage.” Suggesting minor effects to groundwater. “Major effects would be limited to the groundwater area (i.e., around MWH-A17 and SRK-GM-04S) where antimony and arsenic concentrations are below groundwater standards.” These wells appear to be along Hennessy Creek, upstream of the confluence with Sugar Creek and EFSFSR. These predicted exceedances are concerning.		
Samuel Penney (Chairman)	19396	216	The SDEIS states, “The effects of the infiltration of leachate from the TSF, TSF Buttress, stockpiles and Midnight pit backfill...” However, leachate effects to groundwater from stockpiles isn’t discussed. Please include.	WTR	Stockpile leachate contributions to infiltration are minimal because the stockpiled materials are located on top of the other facility materials and the presence of the stockpiled material is temporary. Comparison of constituents of interest in stockpiled materials (i.e., antimony and arsenic) indicate that the concentrations of these analytes in low grade ores are not significantly different from the development rock materials that make up the TSF Buttress and other facilities.
Samuel Penney (Chairman)	19396	217	Surface Water Chemistry Figure 4.9-21- This figure shows baseline, operations, and post-closure values for each surface water site. Please add that these are average concentrations shown in the tables.	WTR	The use of average values in the figure presentation has been added to Figure 4.9-21 legend.
Samuel Penney (Chairman)	19396	218	This figure shows a predicted dissolved mercury concentration during operations over four times the standard at West End Creek node YP-T-6. The SDEIS states this is because the surface water in upper West End Creek is above the standard under existing conditions due to the diversion of West End Creek around the operations associated with the West End pit. The increase in mercury is concerning; West End Creek fully supports its designated uses. What else could be done to decrease the mercury concentrations to below water quality standards?	WTR	West End Creek is a steep gradient creek with relatively low flow under existing conditions. The creek does not accommodate fish habitat and is a minor contributor to conditions downstream in Sugar Creek.
Samuel Penney (Chairman)	19396	219	Tables 4.9-18 and 4.9-19 provide data for two of the seven sites. It would be helpful to show similar tables for the other sites that show predicted exceedances of water quality standards.	WTR	Please see the data tables in SDEIS Tables 4.9-20 and 4.9-21. The remaining three locations are described in tables and graphically in the referenced source document (SRK 2021).
Samuel Penney (Chairman)	19396	220	Organic Carbon subsection: The SDEIS states the potential impacts of the additional organic carbon added is expected to be low given overall discharge rate is small. This is a qualitative assessment with the potential for OC to cause an increase in methylation. The text in Section 6.4.1.4 (Organic carbon) of the Water Quality Specialist Report provides additional information and should be summarized here to provide additional context. We recognize no organic carbon samples were analyzed in the Water Quality Baseline Study. Organic carbon should be added to future analyses.	WTR	The information from the Water Quality Specialist Report has been added to the EIS document.
Samuel Penney (Chairman)	19396	222	Surface Water Temperature An increase in TSS could also raise surface water temperatures. Please add mention of this and how it could be incorporated into the model/results/interpretation.	WTR	Project activities associated with the repair of Blowout Creek are expected to remove the most significant source of sediment in the Project area. Therefore, sediment loads are not expected to increase relative to existing conditions.
Samuel Penney (Chairman)	19396	223	Please add a legend to Figures 4.9-27, 4.9-28, and 4.9-29 (ex. CW, BT, SS, A, B).	WTR	The abbreviations utilized in the figure graphics have been added to the figure legend.
Samuel Penney (Chairman)	19396	224	The predicted surface water temperatures are elevated in the TSF and TSFB area for certain mine years as well as farther down gradient (see Figures 4.9-27 and -28). This is concerning.	WTR	Comment noted. This is consistent with the impact assessment as presented in SDEIS Section 4.9.2.2.
Samuel Penney (Chairman)	19396	225	4.9.2.4 Model Sensitivity and Uncertainty The SDEIS states, “Incorporation of first-flush chemistry in the model predictions would slightly increase predicted analyte concentrations.” This should be elaborated on (briefly described on page 43 of the Water Quality Specialist Report). Would different analytes exceed water quality criteria? What would the expected concentrations of constituents of concern be? How long would the exceedances last? What would the anticipated or potential effects be?	WTR	The use of first flush kinetic test leaching data is described in SDEIS Section 3.9.4.2 with potential implications for predictive modeling described in SDEIS Section 4.9.2.4.
Samuel Penney (Chairman)	19396	226	The SDEIS states, “Effects of model uncertainty from simulating dissolved rather than total concentrations have not been evaluated, but total concentrations of analytes that appear in particulate form would be greater than the simulated dissolved concentrations.” The report states mercury is found more-so in particulate form rather than dissolved. The surface water quality standard value for mercury is listed in Table 3.9-1 (12 ng/L in total form). “The EPA recommends that a human-health methylmercury criteria of 0.3 mg/kg that is translated to a total-mercury concentration of 2 ng/L in surface water be utilized in the analysis. This recommendation is incorporated into the impacts analyses, but table-reported standard values utilize the 12 ng/L (0.00012 mg/L) representing the lowest	WTR	The geochemical equilibrium model used for water chemistry predictions (i.e., PHREEQC) is the publicly available, accepted modeling code for assessing mining effects on groundwater and surface water. The PHREEQC model utilizes dissolved fraction water chemistry for its calculations. The Site-Wide Water Chemistry Report, cited in the SDEIS and released at the same time as the SDEIS, describes the relationship between total and dissolved analyte concentrations indicating that instances with higher total concentrations are related to storm and snowmelt runoff of the native ground surface. Control measures would be put in place to

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			concentration adopted as a standard.” By modeling the dissolved fraction of mercury, total mercury may very well be higher and exceed the water quality standard, which is in total form. Quantification of total mercury concentrations should be performed in the stream predictions.		manage mine contact water. Therefore, runoff contributions of solids in stream flow would be near the existing conditions.
Samuel Penney (Chairman)	19396	227	Top of page 4-280 3rd bullet: please provide the duration.	WTR	The bullet has been clarified that the duration of exceedances extended to the end of the mining period.
Samuel Penney (Chairman)	19396	228	4.9.3 Mitigation Measures The SDEIS states, “The mitigation measures described below are in addition to the Forest Service requirements and EDFs accounted for in the preceding impact analysis.” It would be helpful to list what these are or include a reference to ensure all the impacts identified have mitigation measures covered (ex. see Table 2-3 of the Water Quality Specialist Report for EDFs). Figure 4.9-29 – Please include a timeframe for this figure, either on the figure or in the text reference (ex. x years post operations). Please also include a legend.	WTR	A reference to the Water Quality Specialist Report table of Forest Service requirements has been added to the text. The timing for the sensitivity analysis presented in Figure 4.9-30 (formerly 4.9-29) has been added to the figure legend.
Samuel Penney (Chairman)	19396	275	● Increases in fine sediment delivered to streams has been shown to negatively alter habitat for Chinook salmon and steelhead spawning and rearing in the SFSR. Both of the action alternatives would deliver sediment to live water from proposed road construction and maintenance, increased traffic use, removal of vegetation, pit highwalls, mining activity, fugitive dust and Project related mass wasting events.	WTR	Comment noted. This is consistent with the impact assessment as presented in SDEIS Sections 4.9.2.2 and 4.12.2.2.
Samuel Penney (Chairman)	19396	308	Water Quality The Stibnite area continues to exhibit impaired water quality due to historic mining activities. No stream on the SGP mine site is considered within acceptable risk levels for chemical contamination. The SDEIS notes most metals analyzed in mine site streams occur at concentrations below water quality standards with the exception of arsenic, antimony and mercury. With concentrations of these metals already elevated, it is unacceptable that water chemistry at the Project continues to further degrade post mine closure for certain reaches that contain listed fish species. As noted in the SDEIS on Table 4.12-4, antimony, arsenic and mercury seasonally increase in YP-T-6 (West End Creek) and YP-T-1 (Sugar Creek) and exceed the mercury analysis criteria for mercury for numerous stream reaches within the Project area. The toxic metalloids arsenic and antimony, either individually or in combination, have caused adverse environmental effects in the vicinity of contaminated mines around the world. Metal contamination in stream waters or sediments can be detected up to hundreds of kilometers from their source, and their presence can impose direct and indirect deleterious health effects on salmonid-bearing watersheds.	WTR	Comment noted. This is consistent with the impact assessment as presented in SDEIS Sections 4.9.2.2 and 4.12.2.2.
Samuel Penney (Chairman)	19396	309	Antimony can be toxic to aquatic life and bioaccumulate in tissue. Ambient water quality for the protection of aquatic life has not been established for antimony so thresholds to fish are not established. It is known that antimony and arsenic is currently exceeding the state criteria listing streams in the project as impaired. The analysis shows that the rock in the pit walls and development or waste rock is capable of leaching antimony and other elements into surface and groundwater in concentrations that exceed water quality criteria.	WTR	An antimony standard of 0.0052 mg/L applied for surface water was based on a drinking water standard. This value is lower than the 0.190 mg/L standard for aquatic life.
Samuel Penney (Chairman)	19396	310	Arsenic is highly toxic to aquatic organisms. Arsenic is a suspected carcinogen to fish and is associated with necrotic and fibrous tissues and cell damage, especially in the liver. Arsenic concentrations currently exceed the analysis criteria in all assessment nodes except YP-	WTR	Comment noted. This is consistent with the impact assessment as presented in SDEIS Section 4.9.2.2.
Samuel Penney (Chairman)	19396	311	Mercury is harmful and biomagnifies in the aquatic food web particularly when it is in the organic form (methylmercury). Dissolved mercury currently exceeds the 2.0E-6 mg/L analysis criteria at six of the ten nodes. Table 4.12-4 in the SDEIS highlights that mercury concentrations will exceed baseline conditions for post project closure.	WTR	Comment noted. This is consistent with the impact assessment as presented in SDEIS Section 4.9.2.2. However, the applicable standard for surface water mercury concentrations is 12 ng/L.
Samuel Penney (Chairman)	19396	314	● There are so many factors that will influence site water chemistry (tailing liner leaks, water contacting development rock, seep and spring inputs, water levels). The level of confidence in stream chemistry modeled data should be discussed and uncertainties highlighted.	WTR	Uncertainties regarding water quality predictions are described in SDEIS Section 4.9.2.4.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Samuel Penney (Chairman)	19396	316	<ul style="list-style-type: none"> Why is the modeling of water chemistry at stream reaches stopped at Sugar Creek? The potential to impact the EFSFSR and SFSR water chemistry should be explored, the downstream boundaries of impacts should include stream reaches below Sugar Creek. 	WTR	Predicted surface water concentrations at location YP-SR-2 downstream of the Stibnite Mine Area are at or below existing conditions for that location (see SDEIS Figure 4.9-25). Therefore, Project-related impacts are not expected relative to existing conditions or water quality standards downstream of that location.
Samuel Penney (Chairman)	19396	317	<ul style="list-style-type: none"> Mine reclamation at Cinnabar mine site should be examined as potential mitigation measures for water chemistry in the EFSFSR due to the Project. 	WTR	The Forest Service is not able to require reclamation of a site not owned by the Project proponent as mitigation for the Project.
Samuel Penney (Chairman)	19396	319	<ul style="list-style-type: none"> If antimony is not mined due to low economic value this would dramatically change the water chemistry model results, this should be discussed and modeled. 	WTR	Mining and production of antimony is a component of the Project as proposed. Therefore, it is considered in the analysis of effects from the proposed activities. The antimony is comingled with the gold ore and must be separated to produce gold.
Samuel Penney (Chairman)	19396	321	<p>As described in the SDEIS, the Project will reduce the quantity of groundwater and surface water within the analysis area. Flow predictions for specific streams and time frames (years) have such wide ranges (i.e., 0-100%), that it is impossible to adequately gauge flow reduction impacts to fish.</p> <p>Mine dewatering would lower groundwater levels around the open pits. The lowered groundwater levels would have the potential to reduce surface water flows in areas where streams, seeps, and springs are recharged from the deeper groundwater aquifer. The impacts of pit dewatering on surface and groundwater resources must be further detailed. Assessment of the total deficit, water required to replenish deficits, and the time estimated for the system to reach equilibrium need to be conducted with specific regard to fish.</p>	WTR	SDEIS Section 4.12.2.2 provides a description of how modifications in surface water flows would affect fish species.
Samuel Penney (Chairman)	19396	322	The SDEIS documents a decrease in stream flows and at the same time recognizes that the mine will need to acquire additional water rights. These water rights may or may not be approved as they are currently being protested. The impacts to fish from reduced stream flows does not seem to encompass the entire water budget needed by the Project activities.	WTR	The effects of the entire water budget as depicted in SDEIS Figure 4.8-3 are incorporated into the analysis of effects on stream flows.
Samuel Penney (Chairman)	19396	326	The 2019 Stream Functional Assessment report uses a ledger system as a tool based on a rating system of Watershed Condition Indicators (“WCI”) and other aquatic resource elements at multiple spatial and temporal scales. It is not a sediment model although it combines results of complex models (e.g., groundwater modeling, stream temperature modeling, water chemistry modeling, etc.) to evaluate impacts of the project. A peer-reviewed, repeatable sediment model must be conducted and incorporated into this analysis, with predictions of sediment loading in all of the impacted reaches and streams at various phases of the mine.	WTR	Sediment associated with the Project would be controlled via management practices and Forest Service requirements that would limit sedimentation to levels typical for Forest Service land use. Therefore, a numerical sediment model is not part of the EIS scope.
Samuel Penney (Chairman)	19396	327	The SDEIS relies heavily on the assumption that BMP’s and regular road maintenance will minimize stream delivery to streams. While the SDEIS notes that the potential exists for increased runoff, erosion, and sedimentation which could result in a sediment load into streams during the building of Burntlog route, however sedimentation would be minimized using BMP’s and required maintenance. As noted in the SDEIS, Table 4.12-6, all stream segments currently analyzed for sediment and turbidity in the project area are currently Functioning at Unacceptable Risk (“FUR”) as defined by WCIs. These streamside roads are currently maintained by Perpetua using BMP’s, however the streams adjacent to these roads continue to be categorized as FUR.	WTR	These stream segments are currently affected by contact with legacy mining activities and sediment generation from unstable bank conditions at Blowout Creek. These sediment generating conditions would be addressed as part of the Project proposal.
Samuel Penney (Chairman)	19396	328	<p>The SDEIS inadequately addresses the addition of new roads and their associated disturbance on aquatic ecosystems. Road density is positively correlated with subsurface fine sediment in adjacent streams. As noted in Table 3.12-7 the streams within the Project site are largely listed as FUR for Road Density/Location. While the SDEIS quantifies Road Density/Location in the baseline section it omits a critical WCI of Road Density/Location in its environmental consequence analysis section. The Burntlog Route would require approximately 15 miles of new access road construction. Numerous roads would need to be constructed within the mine site to access and haul mineralized rock and development rock, however these do not appear accounted for in the SDEIS.</p> <p>The Project would construct 9 miles of new roads for transmission lines, however, the SDEIS fails to describe how the Watershed Condition Indicator for Road Density/Location will be altered by the</p>	WTR	Road density was considered as a component in forecasting Watershed Condition Indicators. For streams listed at FUR under existing conditions, the consideration of additional road development did not alter the listing. SDEIS 4.12.2.2 discusses the effect of road density on aquatic resources.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			Project and what it means for fish if subsurface fines increase in adjacent streams. An analysis of changes to the WCI Road Density/Location is needed in the FEIS.		
Samuel Penney (Chairman)	19396	329	The SDEIS did not include modeling to quantify sediment delivery to streams from upgrading transmission line roads and widening of existing access roads along Johnson Creek during the first two years of the mine. The SDEIS notes that utilities associated with the Project (existing transmission line grades and structure work, right-of-way clearing, new transmission line, and transmission line access roads) would cross 37 different streams and upgrade 63 miles of road. The Johnson Creek route crosses 43 different streams including 27 miles of road that are within 0.5 miles of surface water resources. Johnson Creek road will need to be widened to accommodate mining machinery and traffic. Widening roads and clearing roadside ditches of vegetation has been shown to exponentially increase sediment delivery to streams. Once again it is assumed that BMP's and federal regulations will minimize sediment delivery to streams based on professional judgment with no analysis.	WTR	Sediment associated with the Project would be controlled via management practices and Forest Service requirements that would limit sedimentation to levels typical for Forest Service land use. Therefore, a numerical sediment model is not part of the EIS scope.
Samuel Penney (Chairman)	19396	330	The SDEIS lacks modeled results showing how increases in Project related traffic will impact sediment delivery to streams. The SDEIS notes that during the construction phase traffic would increase by 65 vehicle trips per day and during the mining and operation phase (approximately 15 years) traffic would increase a total of 50 trips per day. It is not clear in the SDEIS if Project related road maintenance traffic is also included in these numbers. Increased vehicular traffic causes sediment detachment and can contribute substantially to stream sedimentation. The Watershed Erosion Prediction Project model allows for several options for road configurations, soil, climate, traffic use, gradient, length, and width as well as fill slope and buffer characteristics. The Tribe recommended that in the FEIS there is analysis regarding impacts of traffic on sediment delivery to streams. All Project related traffic including personnel, supply vehicles and associated road maintenance should be included.	WTR	Sediment associated with the Project would be controlled via management practices and Forest Service requirements that would limit sedimentation to levels typical for Forest Service land use. Therefore, a numerical sediment model is not part of the EIS scope.
Samuel Penney (Chairman)	19396	337	The SDEIS insufficiently analyzes sediment impacts to surface water from factors other than roads. The Yellow Pine pit lake has been acting as a sediment trap for Meadow Creek, the East Fork of Meadow Creek and the upper EFSFSR. With the new fish passage tunnel during mine year 1-23, this will no longer be the case. When the fish passage tunnel is constructed and water is allowed to enter this tunnel, it can be expected that the river's sediment will be released downstream. With a large amount of disturbance proposed, the FEIS needs to include more robust quantification and analysis on sediment delivery to area streams.	WTR	Design features and Forest Service requirements as described in SDEIS Chapter 2 would be implemented to control sediment associated with Project development. Application of these measures is expected to be effective in controlling sediment to levels associated with typical Forest Service authorized roadways and activities. Section 2.4.5.10 describes how existing streams would be managed including the voluntary remediation of the Blowout Creek watershed, which has historically been a major contributor of sediment to the Meadow Creek drainage. Sediment monitoring would be used to assess the effectiveness of these design features and controls on downstream effects on sediment.
Samuel Penney (Chairman)	19396	358	The 2021 BC Stream and Pit Lake Temperature Model report goes into more details about the enhanced riparian planting zone extending 16 - 18 feet from 7 feet and revised to include taller species. This speculative assumption is questionable due to the difficult planting conditions at the altered site. Perpetua understands the challenges of plant survival at this elevation and contaminated soil conditions. It is well known that restoration strategies rarely go as planned. Yet the model is optimistic about the shading and the subsequent lower stream temperatures resulting. There are a lot of questionable assumptions in this temperature model starting with the Stibnite Hydraulic Site Model and relating to the outfall location being undetermined as well as the water treatment plant phasing is preliminary and draft.	WTR	The assumptions incorporated in the prediction of future surface water temperatures are described in SDEIS Section 4.9.2.2 with key uncertainties described in Section 4.9.2.4. Section 4.9.3 described mitigation measures applied to reduce the uncertainties in predicting future water temperature conditions.
Samuel Penney (Chairman)	19396	407	5.8 Surface Water and Groundwater Quantity The Tribe disagrees with the Forest Service's assessment that "there are no RFFAs that have or would affect surface water and groundwater quantity in the CEA." Halofsky and others note that "timing of water availability is likely to shift, and summer flows may decline." The Tribe argues that changes in water supply due to a changing climate should be considered as a potential RFFA. The SDEIS notes that the "effects of these natural changes [regional climate change] cannot be accurately quantified." The Tribe wholeheartedly agrees with this statement; hence, why it is so critical for the Forest Service to carefully consider all impacts and not simply dismiss or not quantify impacts because it is too difficult.	WTR	RFFAs included in the NEPA analysis involve anthropogenic activities that have either been developed or approved. Climate change is considered as part of the direct and indirect effects of the Project as described in the SDEIS in Section 4.4.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Samuel Penney (Chairman)	19396	408	The SDEIS fails to compare water quantity cumulative effects between the No Action Alternative and the 2021 Modified Mine Plan.625 It seems reasonable that the removal of legacy mining materials in contact with surface waters in Meadow Creek and the EFSFSR under the ASAOC Phase I could impact groundwater recharge and/or streamflow gains from groundwater by diverting streams away from their historical channels. Additionally, the Tribe is concerned that the Forest Service dismissed other projects and has not looked at cumulative downstream effects on the EFSFSR, SFSR, and the mainstem Salmon River. The SDEIS should be revised to include these analyses. As the Tribe has commented previously in this letter regarding the SDEIS, the Forest Service's reliance on external agency permitting requirements is inadequate to protect water quantity and the Tribe's treaty-reserved rights.	WTR	The effects of the ASAOC on surface water quality have not been quantitatively assessed and would have a similar effect on water chemistry under the No Action and Action Alternatives. Downstream effects of the Project on stream flow rates are described in SDEIS Section 4.8.2.2 and are not expected to be measurable below the East Fork SFSR confluence with Johnson Creek. SDEIS Section 4.9.2.2. describes that analyte concentrations in streams downstream of the Project are expected to be the same or lower than current conditions.
Samuel Penney (Chairman)	19396	409	5.9 Surface Water and Groundwater Quality As noted above, the SDEIS fails to consider a changing climate as a RFFA in their cumulative effects analysis. Halofsky and others indicate "increased magnitude of peak streamflows will damage roads near perennial streams..., thus affecting...water quality and aquatic habitat." Additionally, "[w]ater quality will decrease in some locations if wildfires and floods increase, adding sediment to rivers."	WTR	Explicit numerical modeling of climate change effects is outside of the scope of the EIS analyses. Potential effects associated with climate change are described qualitatively in SDEIS Sections 4.4.2.2., 4.8.2.2, and 4.9.2.2.
Samuel Penney (Chairman)	19396	414	Assumptions stated in the SDEIS Section 4.12.2.2 are that much of the fish habitat modeling and analysis presented in this section are based on the hydrologic and site-wide water chemistry modeling performed by Midas Gold Idaho, Inc., or its consultants. Predictions generated by groundwater and hydrologic models are associated with a degree of uncertainty and can be limited in their predictive power. Yet many of the results in the SDEIS are based on these models. Errors in the input files of any of the models compound as the models are cumulatively used. So many of the conclusions in the SDEIS are based on problematic simulated model results cited in these comments are reason enough for this mine plan approval should be denied.	WTR	Limitations and uncertainties associated with the numerical models used in the EIS analysis are acknowledged and described in SDEIS Sections 4.8.2.4 and 4.9.2.4. Mitigation measures to address modeling uncertainties are described in SDEIS Sections 4.8.3 and 4.9.3.
Samuel Penney (Chairman)	19396	435	Water Quantity Specialist Report The Water Quantity Specialist Report ("WQSR") states, "maintain instream flows for fish... to the maximum extent practicable." What does to the maximum extent practicable mean? Will Perpetua reduce water use and scale back production?	WTR	The Water Management Plan cited in the SDEIS describes steps to maintain instream flows in the Project area including targeted discharges in Meadow Creek during low flow periods and maintaining water balances through process water recycling.
Samuel Penney (Chairman)	19396	436	The Figure 7-8a blue box is for EOY 12 pit extent for both figures but the areas in blue are different. Please provide additional information to explain this figure. Should the figure on the left be EOY 5 pit extent?	WTR	The blue box's label has been revised to "EOY 5 Pit Extent".
Samuel Penney (Chairman)	19396	437	<ul style="list-style-type: none"> Impacts to Groundwater Levels - The WQSR states, "Lowered groundwater levels in the vicinity of the TSF and TSF Buttress are predicted to slightly reduce flows in underdrain systems constructed below the facilities and their liners..." Impacts to Groundwater Flow - The WQSR states, "The presence of the fully lined TSF and TSF Buttress..." However, in the SDEIS the TSF Buttress is not lined. Please reconcile. How were the models run? There is no figure in this document that shows a liner. 	WTR	The statement regarding the fully lined TSF and TSF Buttress pertains to lining of the top surface of the facilities at closure. This clarification has been added to the EIS. Conceptual representations of the liner systems appear in SDEIS Section 4.9.2.2 and in the Water Quality Specialist Report. A citation to the companion documents has been added.
Samuel Penney (Chairman)	19396	438	The WQSR discusses the reduction in stream flow in Meadow Creek between the TSF and Hangar Flats pit compared to baseline of up to 40% (because the creek is lined so no recharge from groundwater), but that the IPDES permitted outfall will largely offset this by the addition of treated water. How long of a stream section is reduced before the outfall? It would be helpful to have a series of figures that show stream reduction percentages in map view over time.	WTR	The IPDES permitted outfall is upstream of the 0.4 mile long stream segment between the TSF and Hangar Flats pit. While not consolidated on a single figure because of the scale needed to illustrate predicted stream flows, SDEIS Figures 3.8-2 and 3.8-3 show the stream locations that correspond to the stream flow predictions depicted in SDEIS Figures 4.8-11 through 4.8-17.
Samuel Penney (Chairman)	19396	439	Stibnite Gold Project Stibnite Hydrologic Site Model Refined Modified Proposed Action (ModPRO2) Report The Hydrologic Site Model Refined Modified Proposed Action (ModPRO2) Report does not model the filling of the TSF in Mine Year -1, even though the model includes Mine Year -1. This is a concern, as the October 8, 2020 Brown and Caldwell memo on water right diversion rates and volumes mentions	WTR	As depicted in SDEIS Figure 4.8-3 mill demand (i.e., filling of the TSF) starts in Year -1 and was incorporated into the effects analysis.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			filling the TSF in Mine Year-1 may result in the need for mitigation for Forest Service water rights for Wild and Scenic Rivers on the Salmon River. Was a hydrologic model done in order to know this is an issue and that mitigation may be needed? Why wasn't it done with the current hydrologic model for a cumulative effect?		
Samuel Penney (Chairman)	19396	440	Section 3.2.1. For West End pit lake development, the 100-year post-mining SHSM climate scenario is based on historical data from 1918 to 2017. Is this a valid assumption? How might climate change affect these scenarios (more water, less water, precipitation more as rain versus snow, earlier or later peak flows, etc)?	WTR	Explicit numerical modeling of climate change effects is outside the scope of the EIS analyses. Potential effects associated with climate change are described qualitatively in SDEIS Sections 4.4.2.2., 4.8.2.2, and 4.9.2.2.
Samuel Penney (Chairman)	19396	441	TSF consolidation water is treated in the post-mining period through Mine Year 40. What happens if treatment is needed beyond Mine Year 40? Will Perpetua be required to continue treating?	WTR	The volume and water chemistry of mine effluents would be monitored through operations and into the closure and post-closure periods. Water treatment would be required until discharge volumes decreased to minimal flow rates.
R. Skipper Brandt, Ted Linsely, Denis Duman		4	Throughout the site, old tailings piles left by previous mining companies were never properly constrained and currently leach metals into nearby streams and the groundwater, the Modified Mine Plan in the SDEIS plans will include activities to improve water quality, such as removing legacy waste rock, removing old underground workings and removing legacy tailings to reprocess and safely store them. It is very important that if mining operations are approved, these proposed actions to address legacy impacts remain in the final plan for the Stibnite Gold Project. As it stands, the only opportunity on the table today to address legacy waste and contamination of the site is through approval of this project. What is not clear is what will happen if a No Action alternative is selected? Will the current levels of contamination of our Salmon River continue?	WTR	If the No Action Alternative is selected, additional removal of legacy mine wastes from the East Fork SFSR would currently be limited to those included in Phase I of the ASAOC work described in Section 1.3.
R. Skipper Brandt, Ted Linsely, Denis Duman		10	With respect to the chemistry of the tailings deposited into the TSF, chemicals such as mercury, cyanide and arsenic will be neutralized, stabilized or removed as part of the processing cycle before any tailings material is deposited into the TSF, further reducing risk of impacting water quality.	WTR	No further response required. General in nature or position statement.
R. Skipper Brandt, Ted Linsely, Denis Duman		11	Over the past few years, the ongoing study of the Stibnite Gold Project has highlighted the poor environmental conditions that exist today at Stibnite because of past operators. Arsenic levels in the East Fork of the South Fork of the Salmon River are far beyond safe standards. Each year, hundreds of tons of sediment continue to be dumped into the East Fork of the South Fork of the Salmon River and other waterways from Blowout Creek, impacting water quality and aquatic habitat.	WTR	No further response required. General in nature or position statement.
Margaret Conway		1	I am familiar with the mine, as I was a biotech and hydrotech for 30 years on the Payette National Forest, including the East Fork South Fork Salmon River areas. I also produced the air quality monitoring report for PNF, which included finding sources affecting the PNF, such as visibility and particulate matter, precipitation, and fish habitats and lake chemistry monitoring sources. I surveyed high mountain lakes throughout the PNF. I am concerned (as many others are) about acid mine drainage and other contaminants (arsenic, antimony, mercury, etc.) that may be present in the waters discharged by the Stibnite Gold Project. The PNF study stated that water studies showed that the pit lake and the waste rock pile would need permanent water treatment (!) to stop toxic metals from leach into water and contaminating the East Fork. I also read that the Yellow Pine Pit would be drained to mine, before it was partially refilled with rock and "the pit would be shaped then lined with a cover (!) to prevent toxic metals from leaching into Stibnite Lake which the East Fork will flow through (!)". I think your ideas about what would happen to fish and wildlife and water quality have not been studied enough. The idea that the lake and rock pile would need permanent water treatment is unreasonable as is the idea that any cover would be sufficient to protect the East Fork. You are taking an incredible chance that this project would not affect water quality, wildlife, fish, and fish habitat; and could possibly put the adjacent wilderness at risk; and destroy endangered salmon, steelhead and bull trout; and the anadromous streams forever!	WTR	Effects of the SGP on water chemistry, wildlife, and fish/fish habitat are described in SDEIS Sections 4.9.2.2, 4.13.2.2, and 4.12.2.2, respectively. These include assessments of the potential for acid mine drainage and leaching of constituents from mined materials which conclude that the potential for acidic drainage is very low but that controls for leached constituents need to be included in the Project. These controls include water treatment that is expected to be required for a period of up to 40 years plus geosynthetic liner systems over mined materials to limit their contact with meteoric waters and the environment. These effects are based on studies conducted over the past seven years. The SDEIS recognizes the limitations on forecasting future conditions as described in Sections 4.8.2.4 and 4.9.2.4. Mitigation measures to limit forecasting uncertainty are described in SDEIS Sections 4.8.3 and 4.9.3.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			I am against this Project. I think the Forest Service should deny the Stibnite Gold Project.		
Q. Barrett		1	The Stibnite Mine will have irreversable habitat loss + other negative impacts on fish, mammals, vegetation + recreation for over 100 years. This land is home + sacred to the Nez Perce Tribe who use the land for traditional hunting, foraging, + fishing under the protection of treaty. How will the water stay pristine? How will heavy metals not leak? It is wilderness for a reason. How will the habitat of ESA listed species not be harmed? NO FISH TUNNEL.	WTR	The existing condition of the mine site area is a largely unreclaimed historical mining operation site that is not considered wilderness. Protective measures for stream water chemistry and fish/fish habitat are described in SDEIS Chapter 2 with the predicted effects of the Project described in SDEIS Sections 4.9.2.2 and 4.12.2.2, respectively. Further, the potential water chemistry and fish/fish habitat on Tribal Treaty Rights and Interests are described in SDEIS Section 4.24.2.2.
Sharon Morning		2	I also stand with the threatened bull trout. Officials with the Idaho Conservation League cited a fisheries specialist's report indicated "a net decrease in quantity and quality of bull trout habitat would occur" despite Perpetua Resources' plans to remove barriers to fish passage and increasing lake habitat.	WTR	No further response required. General in nature or position statement.
John Rygh		10	<p>Water Quantity and Quality</p> <p>Increasing lack of access to freshwater resources is a well-documented global trend. In terms of essential benefits to humans, freshwater is far more valuable than any amount of gold. The SDEIS analysis of effects to water resources is somewhat improved over the previous DEIS, but the results are still fraught with such a high degree of uncertainty, that the Forest Service will be hard pressed to base any reasonably defensible decisions on it. Future predictions by their nature contain uncertainty, but more thorough analysis could have been done to reduce that uncertainty, yet that did not happen. The reliance on 'industry standard' methods often sets a much lower bar than the "best available science" that NEPA calls for.</p> <p>Way back when that first draft plan landed on my desk at the Forest Service, I told my boss that the FS had better retain the services of some top-notch geochemists and hydrologists well versed in numerical modeling if they hoped to conduct an adequate analysis of the project. I even suggested a few names.</p> <p>Well, that went nowhere and now eight years later it is apparent that this still hasn't been done. Almost all affected resources are linked to water in some way and the predicted effects to those resources are dependent upon predictions of water quality and quantity. These predictions are all based on computer models produced by contractors hired by the project proponent. The lack of any critical review in the SDEIS of the model data inputs, assumptions, conceptualizations, and process steps suggests that either the Forest Service and its NEPA contractors did not have the experience to conduct an in-depth critique, or that they simply accepted the model results at face value. The Forest Service needs to address the following model-related issues, and to do this they need expertise that is currently lacking.</p>	WTR	<p>Limitations and uncertainties associated with the numerical models used in the EIS analysis are acknowledged and described in SDEIS Sections 4.8.2.4 and 4.9.2.4. Mitigation measures to address modeling uncertainties are described in SDEIS Sections 4.8.3 and 4.9.3.</p> <p>The groundwater flow modeling was subject to a third-party review as described in the Final EIS.</p>
John Rygh		12	<p>This particular document was foundational in determining climatology input parameters for the Meteoric Water Balance (MWB), therefore I am prevented from evaluating whether the choice of dataset was appropriate. The Forest Service needs to obtain this document and review the conclusions. A basic problem with the climatology data is the fact that there are only a few years of site-specific data.</p> <p>The alternative PRISM dataset is based on extrapolated precipitation and temperature data primarily from SNOTEL sites far away from the project site. The following excerpt from the Water Quantity Specialist Report raises some questions.</p> <p>A long-term climatological record is not available for the SGP. Therefore, Parameter-elevation Regressions on Independent Slope Model (PRISM) data compared with the National Weather Service and Snow Telemetry (SNOTEL) Secesh Summit site is used to develop average precipitation and temperature estimates (Table 6-1). The Secesh Summit site is located 35 miles northwest of the SGP, at a comparable elevation (Brown and Caldwell 2017).</p> <p>First of all, since the PRISM data is based on SNOTEL data the utility/validity of comparing it with a dependent variable (a single SNOTEL site) is questionable. Then one wonders why the Secesh site was chosen for this comparison. The elevation is only comparable to the valley floor at Stibnite, not the surrounding uplands. The Deadwood Summit SNOTEL site is of similar elevation and much closer to Stibnite than Secesh Summit. Why wasn't this used? It appears that there are many other steps in the</p>	WTR	<p>The elements of the meteoric water balance are provided and described in the Site-Wide Water Balance Report. This document provides the data and conclusions on which further modeling was based.</p> <p>The selection of SNOTEL data was based on identification of a nearby location at a comparable elevation to the Project with a long record of data collection. The PRISM dataset is then able to account for changes in elevation around the area of analysis.</p> <p>The water balance model has a non-proprietary reader that allows inspection of the model data and results.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			MWB model, however the model is proprietary so confirmation of its validity is not possible unless the Forest Service can obtain the program from Brown & Caldwell.		
John Rygh		13	<p>The glaring fundamental flaw in the MWB model is a failure to take climate change into account. The project effects are expected to extend up to 100 years into the future. To rely on a dataset from the present back to 100 years in the past is absurd. Was this a case of overlooking the obvious, or willful ignorance? Having cobbled so many different models together for this analysis, was there some reason why even rudimentary climate projections were not accounted for? All subsequent model outputs rest on this MWB. The term "castles made of sand" comes to mind. The Forest Service needs to demand that climate change considerations are incorporated into all modeling. The latest CEQ guidance (CEQ- 2022-0005) on the matter is clear:</p> <p>As discussed in this guidance, when conducting climate change analyses in NEPA reviews, agencies should consider: (1) the potential effects of a proposed action on climate change, including by assessing both GHG emissions and reductions from the proposed action; and (2) the effects of climate change on a proposed action and its environmental impacts.</p>	WTR	Explicit numerical modeling of climate change effects is outside of the scope of the EIS analyses. Potential effects associated with climate change are described qualitatively in SDEIS Sections 4.4.2.2., 4.8.2.2, and 4.9.2.2.
John Rygh		14	<p>The subsequent hydrologic models suffer from a variety of shortcomings. Sensitivity and uncertainty analyses were done for some, but not all models. Output from one model serves as input for another in many cases, greatly compounding uncertainty. Was this accounted for and quantified? Some models (e.g. the SHSM) are created using the MWB and MODFLOW6, but appear to be coupled in only one direction. It is not clear how evapotranspiration (ET) was modeled in the MWB. It appears that potential ET was used (Site Wide Water Balance, p. 38) instead of actual ET. This introduces significant error in the MWB. The ET tool available for MODFLOW6 may do a better job. The use of monthly timesteps in various models is not particularly useful when analyzing effects to fisheries since hydrologic events (e.g. rain-on-snow events that are expected to increase in frequency with climate change (Espinoza, et. al., 2018) that can have significant impacts to fish habitat are averaged out thus failing to account for their out-sized impacts on channel morphology. Previous recommendations to use fully integrated, physically-based, daily timestep models (of which there are plenty of choices) seem to have been ignored.</p> <p>The Water Quantity Specialist Report at page 85 makes a blanket excuse for failing to adequately evaluate model uncertainty by selectively paraphrasing Rzepecki (2012), claiming it would be too expensive and time consuming.</p> <p>Many of the other, more sophisticated approaches listed above for evaluating model uncertainty can be quite involved and, due to limitations of software and hardware, combined with the budgetary and time constraints of most projects, are still not practical outside of the realm of research (Rzepecki 2012). Rzepecki acknowledges the difficulty of implementing better approaches, but does not consider them impractical and goes on to present a simplified approach that compares favorably with Calibration Constrained Monte Carlo methods. Why was this approach not subsequently investigated? Rzepecki's paper is ten years old and there are likely significant improvements made in uncertainty analysis since then that should be investigated. The expense excuse doesn't hold much water when one considers that Perpetua has just received a huge Department of Defense grant earmarked to conduct further environmental studies. So do it.</p>	WTR	Limitations and uncertainties associated with the numerical models used in the EIS analysis are acknowledged and described in SDEIS Sections 4.8.2.4 and 4.9.2.4. Mitigation measures to address modeling uncertainties are described in SDEIS Sections 4.8.3 and 4.9.3.
John Rygh		15	<p>Other model-related issues</p> <p>The SHSM model boundary is located too close to the YP pit which will produce erroneous groundwater drawdown predictions. The Meadow Creek alluvial aquifer needs further testing. This is the most extensive aquifer in the project area, and expected to supply most of the groundwater for process makeup water, yet it has only received one aquifer test that supports the modeled Gestrin feature.</p> <p>Given the usual heterogeneous properties of glacial outwash deposits, further aquifer testing would seem to be warranted to confirm model predictions.</p>	WTR	<p>The SHSM model boundary is defined by topography. The groundwater drawdown predictions are extensive within the analysis area but subject to limitations and uncertainty associated with predictive modeling. These drawdown forecasts would be confirmed based on monitoring data and modeling updates over the course of the Project.</p> <p>There have been three tests of the alluvial aquifer in the Meadow Creek area that define the hydraulic properties there. The Gestrin Well test was the most recent of those tests and indicated a zone of higher alluvial permeability compared to the other test work.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
John Rygh		16	There are errors in the West End pit lake model. The Meadow Creek Fault Zone was modeled, but the West End Fault Zone (WEFZ) was not. Why? Given the fact that wells drilled into the WEFZ have produced up to 50 gallons per minute of high-concentration arsenic water (Rygh, 2015), and that the fault strikes northeastward under Sugar Creek, the Forest Service should investigate the possibility that it could form a preferential groundwater flow path from the West End pit lake to Sugar Creek.	WTR	Available hydrologic data from the West End area indicates that the fault zone is a low permeability feature with hydraulic parameters represented by the bulk properties assigned in the groundwater flow model.
John Rygh		17	Other hydrologic issues Speaking of the West End pit lake, the SDEIS at 2.4. 7.5 states that if spillage of surface water from the West End pit lake becomes imminent, a portable system would be brought to the site to treat and discharge pit lake water to maintain levels below the rim of the lake and prevent uncontrolled release of lake water. So would this option be in place forever? Would the Forest Service assume responsibility for this after all reclamation bonding has been refunded to Perpetua?	WTR	Responsibility for reclamation, closure, and post-closure activities would be retained by the Project operator until release of the reclamation closure bond. Project effects with the potential to occur over long time periods would require financial bonds to cover those mitigation of those effects.
John Rygh		18	The protection of springs, seeps, and associated groundwater dependent ecosystems (GDEs) appears to be non-existent. Impacts are discussed on page 4-162 of the SDEIS but only springs within the model predicted 10-foot groundwater drawdown would be monitored for any changes. To imagine that effects (e.g. reduction/cessation of flow, death of dependent flora & fauna) would not occur with less than 10 feet of drawdown is completely unrealistic. The proposed solution to this potential problem is to monitor select seeps and springs (SDEIS, p. 4-178) and if groundwater drawdown is not behaving as predicted, then maybe do some more monitoring to maybe figure out what to do about it. Seriously. It appears that this mitigation is designed to validate groundwater modeling, not protect GOE resources. Since Perpetua is diverting water left and right out there, perhaps a mitigation measure of supplemental watering of at least the highest priority (in terms of unique GOE components) is warranted if they become dewatered by drawdown.	WTR	An associated mitigation measure has been added to Section 4.9.3 of the Final EIS.
John Rygh		19	There does not appear to be any discussion of the effects of using geosynthetic liners in stream reconstructions (during & post-mining). Of particular relevance are the implications of curtailing any surface water/ groundwater exchange through the hyporheic zone. Despite the significance of hyporheic zones to aquatic biota, the term is mentioned only in passing in section 3.12.4.1 of the SDEIS where it states: "... there are diurnal variations and hyporheic conditions that protect the eggs and alevins reducing mortality rates. Therefore, while summer temperature thresholds may show zero miles of suitable habitat, this may not be a true representation of the conditions in the river. This appears to suggest that hyporheic flow may act to mitigate the poor temperature predictions of the model while simultaneously questioning the real-world validity of the model. Interesting. Oddly enough no synoptic surveys were conducted in the area streams to determine losing and gaining reaches, so little is known about the existing conditions of groundwater flux. If, for example a lined reconstructed stream replaces a natural reach which was gaining during summer base flow conditions, a source of cold flow upwelling into the hyporheic zone would be lost. This would have deleterious effects on the survival of various salmon id eggs and fry. If the proposed stream channel reconstructions incorporate a significant amount of clean non-PAG/non-metal leaching material into the floodplain within the lined volume, that may act as a limited perched water table/ hyporheic zone that could drain to base flow in the summer months. Whether this would be enough to replace the natural groundwater contribution to base flow would depend on the storage volume of that material. Have any mitigations addressed the potential loss of hyporheic flow?	WTR	The use of geosynthetic liners to inhibit contact between mined materials and surface water for water quality protection also inhibits hyporheic flow of groundwater to surface water. The cooling effects of the hyporheic flow on surface water would need to be replaced via other measures such as riparian shading.
John Rygh		21	Water Quality/ Geochemistry Many issues with the geochemical modeling remain in the SDEIS. Unfortunately I have run out of time to address them, and other commenters have done a more thorough job. I will simply reiterate the concerns expressed by D. Kirk Nordstrom (Nordstrom, 2019) in the original DEIS comments. I have attached a copy of his review. Some of the points he raised have since been addressed in the SDEIS and	WTR	No further response required. General in nature or position statement.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			can be ignored, while I have a strong suspicion that other fundamental problems have not been corrected. Please consider his points carefully, as there a few other geochemists with his level of expertise.		
Samuel Stone		2	<p>Thankfully there is a difference between Colorado in 1850 and mining today: we have proven the risks of mining, and proactively enacted measures to protect our precious watersheds and ecosystems. Legal measures were enacted to protect the South Fork Salmon River. The South Fork Salmon river, threatened by the Stibnite Gold Project, is a major tributary to the Wild and Scenic Main Salmon river. The South Fork Salmon and many sections of its tributaries have been deemed eligible and suitable under the Wild and Scenic Rivers Act by the U.S. Forest Service. These rivers and tributaries are essential to the health of major ecosystems, the health of the people, and the health of the wildlife. Habitants of the South Fork Salmon include endangered Chinook salmon and steelhead, protected by the Endangered Species Act of 1973.</p> <p>The South Fork Salmon also offers essential habitat and breeding grounds for migratory fish. With the South Fork Salmon at the head of the tributaries, it is of utmost importance to conserve and protect the precious water for everyone downstream. Completing and operating the mine would put Perpetua Resources Corp. at substantial risk for litigation in violation of the Endangered Species Act, the Wild and Scenic Rivers Act, Clean Water and Air Acts (CWA, CAA), and the National Environmental Policy Act (NEPA) for various crimes against the environment and its inhabitants (Coriell et al. 2020).</p>	WTR	No further response required. General in nature or position statement.
Deborah Trent		1	<p>I am commenting about what appears to be a major shift in direction from the mining of gold, to the mining of Antimony. The recent large sum of money from the US Department of Defense to Perpetua Resources to do an environmental and engineering studies on antimony trisulfide, has me very concerned.</p> <p>There has been recent research about Antimony in 2021 by a group of International Scientists (see enclosed document: Environment International) that proves that the mining of Antimony is potentially toxic to ecosystems and public health via the accumulation in the food chain.</p> <p>However, there are gaps in understanding how poisonous and carcinogenic it is. Also unclear is what are the mechanisms that cause the toxicity.</p> <p>Antimony in certain biochemical states is one of the most explosive elements on earth! The transportation, storing, and processing of it is very dangerous. Will it be stored on site? If not where and what kind of transport in and out of the mountains and on our Highways 55 and 95 would permit it? What if there was a fire in the area that would come into contact with it? OR God forbid, an act of terrorism?</p> <p>If Antimony leaches into the South Fork of the Salmon or Antimony dust particles build up in the soils, how would this affect fish, wildlife, and the entire ecosystem for years to come?</p> <p>It seems to me that there is no amount of money in the world that would cover all these "what ifs" with a 100% guarantee that some sort of event could be avoided. Any of these situations could happen and the close proximity to our communities and Wild and Scenic Salmon River, would be complete devastation.</p> <p>The RISKS OUTWEIGH THE BENEFITS here. This is a short term bad decision that could have very irreversible long term damaging consequences.</p> <p>Please, chose the NO- Action alternative! I do not see any way that the Stibnite Mine should be allowed to proceed.</p>	WTR	<p>The handling and transportation of an antimony concentrate that would be produced by the Project are described in SDEIS Section 2.4.5.7. Measures to containerize and limit exposure risk of produced antimony concentrate have been incorporated into the Project. Antimony concentrate consists primarily of antimony sulfide minerals and is not explosive in that form.</p> <p>Controls and effects of antimony leaching from mined materials to surface waters are described in SDEIS Section 4.9.2.2.</p> <p>Controls and effects of antimony present in dust generated from Project activities are described in SDEIS Section 4.3.2.2.</p>
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		1	<p>1.0 Surface Water and Groundwater Quantity and Surface Water and Groundwater Quality</p> <p>We found Sections 3.8 and 3.9 overall provide a reasonable characterization of water quality and quantity for existing water resource conditions at the SGP site. Sections 3.8 and 3.9 conveyed the existing environmental conditions accurately. The summary of baseline surface water and groundwater monitoring data from recent years, as well as, the vast information contained in agency reports and published technical papers yields an appropriate representation of the groundwater and surface water</p>	WTR	No further response required. General in nature or position statement.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			conditions at the SGP. Particularly, we appreciate the discussion of the extensive testing and knowledge of groundwater in Section 3.8. Comments on these two sections are in Attachment A.		
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		2	<p>2.0 Calculation of Percent Difference in Streamflow</p> <p>The discussion in the Surface Water Quantity subsection of Section 4.8 beginning on page 4-163 and including Table 4.8-4 should be clarified. It is difficult to replicate the values from the cited source and values presented should be percent change, (i.e., (MMP – EC)/EC) and show the direction of change.</p> <p>Similarly, references to relative percent difference should be replaced with percent change and the title of Table 4.8-4 should be modified to describe the calculation performed, such as “Average Monthly Percent Change in Stream Flows during the Mine Operations Period”. Additionally, please clarify if the row labeled “Maximum Monthly Reduction” in Table 4.8-4 is maximum reduction in cubic feet per second (cfs) or a maximum percent change. A minimum percent change and the durations and periods of such occurrences would be helpful to assess impacts. Lastly, please verify calculations to confirm values are correct and describe the calculation performed for transparency.</p> <p>The description also reads as biased toward maximum negative impact without a description of duration, actual magnitude of change in flow rate, and minimum impact or positive impact. The percentages used can be misleading because there is a not a description of the actual change in flow.</p> <p>Please clarify this information with a presentation of the duration of maximum impact and add magnitude of change to the discussion.</p>	WTR	<p>Table 4.8-4 has been clarified to indicate that the maximum monthly reduction is a maximum percent change. Other items on the table provide an appropriate description as presented.</p> <p>The intention of the table is to provide information as to the locations where stream flows are affected by the Project and the relative magnitudes of those effects. Information regarding the durations of effects are presented in Figures 4.8-11 through 4.8-17.</p>
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		3	<p>3.0 Discussion of Groundwater Drawdown</p> <p>The discussion in the Impacts to Groundwater Flow subsection of Section 4.8 describes groundwater level drawdown. Perpetua Resources largely agrees with the interpretation and discussion. A point of clarification in the discussion surrounds the depictions of groundwater drawdown associated with dewatering in the Hangar Flats and Yellow Pine pit areas where changes in existing topography are not considered. Not including discussion of this important change in topography may lead to interpretations that groundwater levels do not recover and remain depressed even at 100 years post-mining (SDEIS, Figure 4.8-9).</p> <p>Groundwater level drawdown is calculated as the difference between groundwater elevations in the existing conditions and groundwater elevations measured or predicted at a future date. It is important to recognize that existing conditions groundwater elevations reflect levels of saturation in consolidated and unconsolidated materials. If those materials are removed by mining, groundwater elevations are necessarily lowered. This condition does not mean that groundwater levels in the post-mining period remain at a great depth below the post-mining surface topography. In fact, the depth to groundwater in locations where materials will be removed may be similar to depths below ground surface during existing conditions.</p> <p>The inactive cells in Figure 4.8-9 are areas where proposed mining will remove geologic materials, lowering the topographic surface. Cells cannot be deleted from the model, but they can become inactive, and simulation of the groundwater surface is then characterized in the underlying active cells.</p> <p>The areas of greatest persistent drawdown generally coincide with these mined out areas, creating an easily misunderstood depiction of the state of recovery of the groundwater system post mining, whereas the trough-like areas of significant drawdown represent changes from the existing conditions groundwater levels without regard to changes in topography rather than depression of the post-mining water table. Thus, the general character of groundwater flow through the mining area is anticipated to be similar to existing conditions in the post-mining period. Perpetua Resources suggests that an interpretation of groundwater levels include a discussion of topographical changes and changes in depth to groundwater to further qualify the information presented.</p>	WTR	<p>The role of topographic changes in depth to groundwater interpretations in the areas that have undergone permanent topography changes has been added to the Section 4.8.2.2.</p>

Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		4	4.0 Groundwater Dependent Ecosystems The effects of dewatering on groundwater dependent ecosystems (GDEs) are discussed in the SDEIS in Section 4.9 and shown in Figure 4.8-10 as the presence of seeps and springs that are within the predicted extent of the 10-foot groundwater drawdown contour. While text on page 4-162 provides discussion on the uncertainties associated with the 10-foot drawdown contour, the visual depiction on Figure 4.8-10 and the legend to that figure do not capture those uncertainties, including that impacts to specific seeps or springs would depend on the degree of interconnection between the perennial surface water and the aquifer affected by mine-related pumping. It should also be noted that many of the GDEs depicted on Figure 4.8-10 are within the mine disturbance footprint and will be directly lost during construction and should not be double counted by including them with GDEs with a potential to be affected by dewatering and water supply pumping. Perpetua Resources suggests that the document should reiterate the uncertainty with the 10-foot contour, discuss interpretation of the 10-foot contour, and show only the seeps and springs that will physically exist after mining and reclamation.	WTR	The uncertainties in predicting groundwater drawdown effects on groundwater dependent ecosystems are described in Section 4.8.2.2. These uncertainties are associated with each site-specific relationship between a GDE and local groundwater. These site-specific relationships typically cannot be determined until the groundwater aquifer is affected by large scale pumping for a period of time. Therefore, they are not currently known and not represented on Figure 4.8-10 which presents the conservative extent for GDE effects. The figure also depicts the stream locations that would be within the areas of surface disturbance so that these areas can be differentiate from locations with groundwater drawdown outside the disturbance footprint.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		5	Paragraph 3 on page 4-151 omits that the groundwater model also predicts streamflow. While baseflow is described in the 4th bullet of the last sentence, this neglects to include runoff contributions to streamflow and the predictions of peak flows in the annual hydrograph. The suggested clarification to the sentence is "...4) streamflow from groundwater discharge and runoff."	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		6	The idea of a steady-state calibration is inaccurate. The model was calibrated to transient groundwater level and streamflow calibration targets. Steady-state calibration is discussed in the last sentence of the fourth paragraph on page 4-154. Steady-state calibration should be struck.	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		7	As well, the third paragraph on page 4-152 incorrectly states pre-mining steady state conditions and transient conditions associated with the pumping test. While the model was calibrated to the transient conditions of the pumping test, the model was also calibrated to the transient conditions of groundwater level in the monitoring wells and streamflows. A suggested correction to the statement is, "Model calibration was accomplished using a process that included transient simulation of pre-mining conditions followed by localized calibration of transient response to pumping tests."	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		8	The last sentence of the third paragraph on page 4-152 is mostly correct but would benefit from additional detail. The suggested revision is "...locations by varying input to the Meteoric Water Balance (MWB) including precipitation bias, deep percolation rate, and porosity coupled with variation in MODFLOW of horizontal hydraulic conductivity, specific yield and specific storage within ranges of measured values for each parameter in each of the modeled hydrologic units."	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		9	Elements in addition to the partitioning of unconsolidated dominated areas and bedrock dominated areas are included in the MWB. The Lower East Fork of the South Fork of the Salmon River (EFSFSR), Upper EFSFSR, Meadow Creek, and Sugar Creek were calibrated for precipitation bias and temperature was adjusted based on elevation. The discussion of the components of the MWB in the last paragraph on page 4-151 continuing into the first paragraph on page 4-152 is incomplete with the omission of components. Perpetua Resources suggests that this additional detail is added for completeness.	WTR	Revision not accepted. The SDEIS Section 4.8.2.2 summarizes the more detailed calibration information which can be found in the referenced model documentation.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		10	6.0 Discussion of Groundwater Model Sensitivity The discussion of groundwater model sensitivity would be significantly improved by simplifying clarifying misstatements and being directly applied to the Stibnite Hydrologic Site Model (SHSM). The following sections provide recommendations to make the groundwater model sensitivity discussion focused and to increase accuracy.	WTR	General sources of model uncertainty are included in the SDEIS Section 4.9.2.4 because they are applicable to the use of model predictions to evaluate Project effects.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			Some of the description in this section is inapplicable to the SHSM and it is suggested that the following be removed to avoid potential confusion: • The second set of bulleted items on page 4-175 are not specific to the SHSM and don't add to the description of uncertainty relevant to the SDEIS.		
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		11	The first 2 paragraphs on page 4-176 are not relevant to the SHSM. An approach is discussed of altering a model through a sensitivity analysis process and recalibrating prior to use for predictive purposes. The SHSM used for predictions during and following mine operations was not altered by the sensitivity analysis. These two paragraphs should be deleted to avoid potential confusion around the use of the SHSM and the role of the sensitivity analysis that was performed.	WTR	The first paragraph on SDEIS page 4-176 notes the limitations of using sensitivity analyses when the modification of model parameters results in de-calibration. This paragraph has been retained while the following paragraph has been removed as it reiterates the content of the first paragraph.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		12	Similarly, the third paragraph on page 4-176 points out that while there are other approaches to uncertainty evaluation, they are not typical nor practical for model applications such as the SHSM. Since these alternative methods were not used for evaluating uncertainty in the SHSM this discussion seems out of place and not relevant to the discussion of uncertainty specific to the SHSM and should be deleted to avoid confusion.	WTR	The SDEIS examines the range of model predictions as indicated via sensitivity analyses. Therefore, the limitations of sensitivity analyses are included in the discussion in SDEIS Section 4.8.2.4. The rationale for not applying other approaches is responsive to other comments on the modeling that seek application of these more intensive approaches.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		13	The next paragraph (paragraph 4 on page 4-176) includes an assertion that "Parameter value selection for the hydraulic characteristics simulated in the SGP hydrologic model is the primary source of uncertainty..." for the SHSM. A reference that supports this conclusion is not included and this was not a conclusion of the SHSM calibration report (Brown and Caldwell [BC] 2021e) or sensitivity analysis report (BC 2021h). The SHSM sensitivity analysis has a contrasting conclusion and demonstrates the model is not sensitive to bedrock hydraulic conductivity or specific yield. Many of the scenarios tested using substantially higher bedrock hydraulic conductivity resulted in a poorly calibrated model. A reference supporting the conclusion in the SDEIS should be included or the statement revised to accurately represent the technical papers cited in this comment.	WTR	The text is appropriate as written and supported by the information presented in Brown and Caldwell 2021h.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		14	The final conclusion in paragraph 4 on page 4-176 is that the "...bedrock aquifer hydraulic characteristics are important because bedrock-hosted groundwater is extensively present throughout the Analysis Area". This statement is not referenced and is not supported by the Hydrologic Conceptual Site Model (HCSM), or the results of aquifer testing provided in the SHSM model report (BC2021e) and the SGP Hydrogeologic Data Adequacy Review (BC 2021g). Specifically, the HCSM includes bedrock groundwater flow present, in any substantial quantity, in the transition zone only (SHSM layer 3) and the deeper bedrock zones are substantially less permeable and no significant groundwater is present (SHSM layers 4 and 5). The sensitivity analysis clearly demonstrates that increasing hydraulic conductivity in SHSM layers 4 and 5 results in a poorly calibrated model that would be unsuitable for use in evaluating mine impacts. Perpetua Resources recommends that this sentence be deleted.	WTR	No revision made. Bedrock groundwater is present throughout the area of analysis.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		15	Paragraph 6 introduces a comparison of pit dewatering without the context discussed in previous paragraphs establishing the poorly calibrated condition of the SHSM under the increased hydraulic conductivity conditions. To avoid misunderstanding the pit dewatering comparison the following text should be added, "This comparison of pit dewatering rates illustrates the conclusion that a very poorly calibrated model is required in order to generate pit dewatering rates that are substantially different from those estimated by the fully calibrated SHSM." The calibrated SHSM predictions for pit dewatering are therefore suitable for evaluating mine impacts because "... there are no substantially different combinations of input parameters that would result in a more closely calibrated model and thereby potentially change predictions of future mine impacts. (BC2021h)."	WTR	No revision made. The intent of the SDEIS Section 4.9.2.4 is to provide some context around the range of potential pumping rates.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		16	Paragraph 7 on page 4-176 that continues into first paragraph on page 4-177 and the second paragraph on page 4-177 speculate on potential impacts of simulations made using a model based on hydraulic parameters other than those in the fully calibrated SHSM. This discussion is potentially misleading because the predictions were made with a poorly calibrated model, and are, by definition, untested and include potentially unacceptable uncertainties. Because of the uncalibrated model condition of these sensitivity analysis scenarios, the dewatering comparisons and inferred impacts that form the basis of	WTR	No revision made. The intent of the SDEIS Section 4.9.2.4 is to provide some context around the range of potential pumping rates.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			these paragraphs do not add to the understanding of uncertainty in the calibrated SHSM. These two paragraphs should be deleted.		
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		17	<p>7.0 Discussion of Water Rights</p> <p>The description of water rights in section 4.8 is generally accurate but could benefit from some additional clarifications. We suggest that discussion surrounding the water rights application status, description of the application, description of the proposed mitigation plan, and the state and federal instream flow water rights could be provided in greater detail. As well, an explanation of the diversion rates cited would provide greater clarity. Suggested comments on each of these items is below.</p> <p>The water right application status is described in the future tense with phrasing such as “Perpetua plans to apply” and “After a water right application has been filed”. This tense is not current now and will not be current when the FEIS is published. The water right application was submitted to the Idaho Department of Water Resources (IDWR) in October 2021. Since that time, the application has been in review, posted for public comment and Perpetua Resources has been working to address issues raised during public comment. We suggest that the phrasing of the application submittal status be updated to accurately describe current status with wording such as “Perpetua submitted a water right application in October 2021...” and “IDWR is performing an analysis...”.</p>	WTR	The verb tense around the water rights applications has been modified per the comment.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		18	The description of the Idaho Water Resource Board (IWRB) and federal minimum instream flow water rights would benefit from additional detail. It is not stated that Perpetua Resources’ water right application is within the subordination clause of the water right since authorization is being sought for industrial beneficial use. Currently, it is difficult to understand how the IWRB and federal reserve water right would impact Perpetua Resources application. Further, paragraph 5 on page 4-174 states, “...and up to 8.2 cfs of new non-domestic, commercial, municipal, and industrial uses”. This does not apply to Perpetua Resources; however, this is not stated. In the discussion of Water Right 77-14190 and minimum steam flow on the South Fork of the Salmon River (SFSR), the description could be improved by stating, “Instream rights on the SFSR and the EFSFSR are subordinate to all future domestic, commercial, municipal, and industrial (DCMI) uses. There is additional allowance for non-DCMI uses; however, this does not apply to Perpetua Resources because the water right application seeks industrial beneficial use. Perpetua Resources water right applications are within the allowance of the IWRB instream rights.” Additionally, the IWRB Water Right 77-14174 is not identified by water right number in the discussion of the SFSR minimum flow water right. Finally, domestic, commercial, municipal, and industrial uses are commonly referred to as DCMI and we suggest using this more recognizable wording.	WTR	No revision made. The description of water rights in Section 4.8.2.2 is consistent with the relevant water rights Orders. The EIS analysis does not draw any conclusions regarding Perpetua's water rights applications or the IDWR review and decision on those applications.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		19	Similarly, the discussion of the Federal Reserve Water Rights for the Salmon Wild and Scenic River (WSR; 75-13316 and 77-11941) would improve with additional detail of the water right and discussion of how this could impact Perpetua Resources. The Federal Reserve water rights are subordinate to up to 150 cfs of new diversions; however, diversion to storage is explicitly not subordinated. Perpetua Resources water right application is within the diversion allowance of the water right and Perpetua Resources proposed diversion is not junior to the Federal Reserve water rights. However, diversion to storage is a junior use to the Federal Reserve water rights.	WTR	No revision made. The description of water rights in Section 4.8.2.2 is consistent with the relevant water rights Orders. The EIS analysis does not draw any conclusions regarding Perpetua's water rights applications or the IDWR review and decision on those applications.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		20	The first paragraph on page 4-175 introduces water right mitigation measures that will be determined by IDWR. This is correct; however, the discussion does not specify conditions when mitigation would be required, does not state that Perpetua Resources has submitted a proposed mitigation plan, and does not describe the proposed mitigation. Mitigation is anticipated to be required only when Perpetua Resources is diverting to storage and the minimum instream flow in the Federal Reserve Water Rights for the Salmon WSR (75-13316 and 77-11941) are not being met. This condition is expected to be a limited occurrence because diversion to storage is modeled to be required only during initial fill of the tailings storage facility (TSF). Perpetua Resources’ proposed mitigation plan is to mitigate diversion to storage by non-use of irrigation water rights on the Salmon River and Morgan Creek that authorize diversion of up to 10.75 cfs. The proposed mitigation plan over mitigates 1) annual diversion volume to storage, 2) length of affected WSR stream length and, 3) duration. Perpetua Resources suggests that describing the	WTR	No revision made. The EIS analysis acknowledges the potential for mitigation measure requirements associated with the IDWR review and decision on Perpetua's applications but does not draw any conclusions regarding their details which are pending decision by IDWR and are not included in the SGP description reviewed by the Forest Service for this EIS.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			proposed mitigation, benefits, and conditions when mitigation is required will make this discussion more complete.		
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		21	With the submittal of Perpetua Resources’ application, the description of the water right can include elements of the water right application. Important elements to include, in addition to the diversion rate, is the diversion to storage rate (9.6 cfs), the annual storage volume (600 acre-feet), and the beneficial use (industrial). These elements are critical to understand how the water right interacts with the minimum instream flow water rights.	WTR	The elements of the water rights application have been added to the revised text.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		22	<p>Finally, the discussion cites diversion rates that are different from the diversion rate seeking authorization of 9.6 cfs. Diversion rates of 4 cfs, 4.05 cfs, and 9.68 cfs are used in the text as,</p> <ul style="list-style-type: none"> • “Typical rates of surface water diversion during the build-up of project water inventory would be approximately 4 cfs” • “The maximum diversion rate under existing and proposed surface water rights is 4.05 cfs...” • “...maximum diversions proposed by Perpetua from all sources and uses would be 9.68 cfs...” <p>It is not transparent how these diversion rates were estimated and how the values were applied. A discussion of the 4 cfs and 4.05 cfs and how these apply to the 9.6 cfs sought in the water right application would help clarify the first two bullets. The 9.68 cfs could be a typo because the total authorized water diversion for industrial and mining purposes with existing and proposed water rights is 9.86 cfs. We suggest that the generation of the values be described and why these are different from the diversion rate in the water right application or use the diversion rate in the water right application and existing water rights for clarity.</p>	WTR	<p>The value of 9.68 cfs has been corrected to 9.86 cfs.</p> <p>The discussion of typical diversion rates has been revised based on Brown and Caldwell 2021j (technical memorandum from December 2021 added to reference list).</p>
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		23	<p>8.0 Mercury Water Quality Standards</p> <p>In the Ore Stockpiles sub-section of Section 4.9.2.2 on page 4-190 in paragraph four there is reference to a non-regulatory water quality value calculated by the United States Environmental Protection Agency (EPA), “Other metal leaching concentrations were predicted to be below surface water standards with mercury concentrations between 7 nanograms per liter (ng/L) and 11 ng/L (SRK Consulting, Inc. [SRK] 2021a, Appendix A), but above the 2 ng/L concentration calculated by the EPA”. The meaning of the final phrase of this statement is not clear, but Perpetua Resources is not aware of any “calculation” of a 2 ng/L concentration criteria by EPA. Idaho’s approved Water Quality Standards (WQS) include a fish tissue methylmercury criterion (0.3 milligrams per kilogram) for the protection of Human Health, which Idaho asserts is also protective of aquatic life.</p> <p>The WQS also indicate that, for Clean Water Act purposes, the 12 ng/L total recoverable mercury value from the 2004 Idaho Administrative Procedures Act regulations continues to apply. The Implementation Guidance for the Idaho Mercury Water Quality Criteria published by the Idaho Department of Environmental Quality in 2005 notes a value of 2 ng/L total mercury as the most stringent extreme in a sensitivity analysis to evaluate its methylmercury criteria, and then points to how overly protective such a value would be. Comments from EPA on documents prepared by Perpetua Resources suggested using a 2 ng/L value, but that value is not an adopted or approved water quality criterion. Perpetua Resources notes that National Pollutant Discharge Elimination System permits recently written by EPA for mines in Idaho contain daily discharge limits such as 26 ng/L (US Silver Coeur and Galena Mine – 2019), 53 ng/L and 57 ng/L (Hecla Grouse Creek Mine – 2018), and 40 ng/L, 99 ng/L, and 130 ng/L (Hecla Lucky Friday Mine - 2019), all of which are well above the concentrations predicted for the SGP. Based on the promulgated standard and this additional information, predicted mercury values should only be compared to the applicable standard (i.e., 12 ng/L) and the reference to 2 ng/L should be removed.</p>	WTR	The discussion of the 2 ng/L criteria was included per information provided to the Forest Service by EPA. However, 12 ng/L remains the relevant standard for comparison. Comparisons are made to the 2 ng/L concentration because EPA utilizes that value as an indicator for the potential for methylmercury to accumulate in fish tissue to a concentration above the fish tissue criteria.

Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		24	<p>9.0 Acknowledgement of Benefits to Water Quality</p> <p>There are multiple occurrences of the SDEIS not acknowledging the positive impacts to water quality that will be realized because of the Project. Section 4.9 appears to be biased without full disclosure of these benefits. There is language in the section that describes significant improvements in water quality as “similar to existing conditions” where, in reality, modeling suggests that improvements can be as much 30 percent to 40 percent or more. The qualification of these benefits as similar to existing conditions understates anticipated improvements. Additionally, there is at least one instance where order of magnitude improvements are not recognized or discussed. Overlooking positive impacts and downplaying the magnitude of improvement renders Section 4.9 not a fully representative effects analysis and demonstrates a bias in the discussion. These occurrences are easily remedied, and Perpetua Resources has commented on these in the comment table with additional detail in the bullets below.</p> <ul style="list-style-type: none"> • In Section 4.9.2.2 on page 4-190 there is discussion of runoff chemistry and toe seepage that are predicted to be above the strictest water quality standard. There is, however, no discussion of improvements to groundwater. It should be stated that the groundwater quality predicted below the TSF Buttress is significantly improved compared to the current conditions as a result of removing the Hecla Heap and spent ore disposal area (SODA)/Bradley tailings. Groundwater arsenic and antimony concentrations are predicted to be an order of magnitude lower than the current conditions as a result of the mine plan. Furthermore, there is a significant reduction in infiltration from the TSF Buttress during the post-closure period as a result of placement of a geosynthetic cover and infiltration is reduced to near zero. The following text should be added to provide a full account of the predicted changes to groundwater in the Hangar Flats area: “Upon placement of the geosynthetic cover on the TSF Buttress, infiltration is significantly reduced and arsenic and antimony concentrations in groundwater decrease but remain elevated above groundwater standards due to the recharge of residual water within the TSF Embankment and Buttress. However, the predicted arsenic and antimony concentrations in groundwater during the post-closure period are significantly lower than the existing conditions due to the removal of legacy facilities (Hecla Heap and SODA/Bradley tailings) during mining. Based on average concentrations from MWH-A04, arsenic and antimony in groundwater are 1.8 and 0.06 milligrams per liter respectively under existing conditions. <p>Arsenic and antimony concentrations are predicted to be an order of magnitude lower for the postclosure period due to the removal of the legacy facilities but still elevated above the groundwater standards and background groundwater quality as defined by MWH-A01.”</p>	WTR	<p>The SDEIS describes water quality conditions as similar or improved compared to baseline conditions except for the case of the Hangar Flats and Yellow Pine Pit backfills that have the potential to increase analyte concentrations in groundwater.</p> <p>The predicted groundwater concentrations under the TSF buttress are described in SDEIS Table 4.9-4 and Figure 4.9-4. A sentence indicating that these concentrations have decreased based on comparison to MWH-A04 has been added to the paragraph referencing Table 4.9-4 and Figure 4.9-4.</p>
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		25	<p>In Section 4.9.2.2 on page 4-243, the discussion of groundwater chemistry is focused on potential negative impacts without mention of the significant improvement in groundwater quality in the Meadow Creek valley resulting from the removal of legacy material early in the mine life and pumping of contaminated groundwater in the dewatering process that is replaced with clean, unimpacted water into the currently contaminated area. The improvement of groundwater quality in the Hangar Flats area resulting from the removal of legacy facilities is not clearly captured in discussion of groundwater impacts. The following is a suggested replacement of the second paragraph on Page 4-243: “Effects of the TSF, TSF Embankment and Buttress, and stockpiles leachate infiltration on receiving alluvial groundwater were summarized in Figures 4.9-4 and 4.9-8.</p> <p>Limited infiltration from the lined TSF results in negligible changes to groundwater parameter concentrations under the TSF and no constituents exceed groundwater quality standards.</p> <p>Infiltration from the unlined TSF Buttress is predicted to result in an increase in groundwater analyte concentrations. Specifically, mixing of infiltrated leachate with alluvial groundwater is predicted to result in antimony and arsenic groundwater concentrations greater than unimpacted groundwater and both constituents are predicted to be above groundwater standards. Both arsenic and antimony concentrations decrease in groundwater after placement of the geosynthetic liner but remain above the groundwater standards. However, post closure arsenic and antimony concentration are predicted to be an order of magnitude lower in comparison to existing groundwater conditions due the removal of legacy</p>	WTR	<p>The text has been revised to indicate that compared to monitoring well MWH-A04, analyte concentrations have decreased compared to baseline conditions.</p>

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			facilities (e.g., Hecla Heap and SODA/Bradley tailings), representing an overall net improvement to groundwater quality as a result of mining activities.”		
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		26	In Section 4.9.2.2 on page 4-248, the benefits to surface water chemistry during operations and the post closure period are minimized and incorrectly quantified. The water quality improvement with reductions in arsenic and antimony at YP-SR-4 should be quantified. Reductions are as much as 40 percent in the post closure period and greater during operations. The statement that, “Immediately downstream of the Yellow Pine pit on the East Fork SFSR at node YP-SR-4 (above the confluence with Sugar Creek), predicted surface water chemistry is similar to existing conditions with some variability in predicted antimony, arsenic, and mercury concentrations during the operating and initial closure period (Table 4.9-19 and Figure 4.9-23)” does not accurately portray the modeling results.	WTR	The text has been revised to read that "... predicted surface water chemistry is similar to existing conditions with reduced concentrations of antimony and arsenic during the operating and post-closure periods."
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		27	In Section 4.9.2.2 on page 4-251, the statement regarding surface water quality predictions for YPSR-2, “Similarly, predicted arsenic concentrations decrease relative to existing conditions during the operating period then recover to a concentration comparable to existing conditions in the postclosure period”, is misleading. The results show arsenic and antimony at YP-SR-2 during post-closure conditions are significantly lower (30 percent to 40 percent) relative to existing conditions. This positive impact should be clearly stated and quantified.	WTR	The text has been revised to indicate that predicted arsenic and antimony concentrations recover to a concentration below existing conditions.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		28	In Section 4.9.2.2 on page 4-252, the SDEIS states that the “Effects of the project on surface water concentrations are expected to be negligible relative to applicable standards and calculated human health criteria, permanent, and localized”. However, it should also be acknowledged that there is a substantial improvement in surface water quality compared to existing conditions because of this project. The Project’s positive impact is downplayed in this discussion.	WTR	The SDEIS describes water quality conditions as similar or improved compared to baseline conditions except for the case of the Hangar Flats and Yellow Pine pit backfills that have the potential to increase analyte concentrations in groundwater (i.e., the groundwater sub-section of SDEIS Section 4.9.2.2).
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		29	10.0 Interpretation of Particle Tracking and Groundwater Impacts Downgradient of Yellow Pine Pit The particle tracking results are not applied correctly in the discussion in Section 4.9.2.2 on page 4-244. Particle tracking does not account for changes in chemical mass in groundwater that naturally occur as the result of chemical interactions with minerals in the ground and dispersion of chemical mass as groundwater moves through the ground. Therefore, even though 2 percent of the particles were estimated to originate from the backfill, this does not automatically relate to groundwater concentrations, nor does it speak to the potential for the pore water to degrade groundwater. The potential to degrade groundwater depends upon the existing groundwater chemistry and how different it is from the pore water leaving the backfilled pit. In the case where the existing groundwater is already impacted and concentrations are higher than in the pore water, there could actually be an improvement in existing groundwater conditions. This potential to improve previously impacted groundwater downgradient of the YPP needs to be acknowledged.	WTR	The SDEIS describes water quality conditions as similar or improved compared to baseline conditions except for the case of the Hangar Flats and Yellow Pine pit backfills that have the potential to increase analyte concentrations in groundwater. Water movement from the pit areas downgradient is used to conservatively assess potential analyte concentrations downstream. Modification of pore water chemistry based on reactions with downgradient groundwater and aquifer material was conservatively not assessed in describing potential groundwater chemistry effects.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		30	Furthermore, the conclusion that some areas would see major negative effects is premised on the assumption that these areas are not already impacted by legacy mining materials and in-situ mineralized rock. The cited wells (i.e., MWH-A17 and SRK-GM-04S) are only drilled to about 100 feet and are screened at elevations of 6100 feet and 6040 feet respectively; approximately the same elevation as the existing pit lake (6040 feet) and elevation of future backfill. These screen elevations may not be sufficiently deep to adequately assess existing water quality of the receiving alluvial or bedrock aquifer where it could be impacted by pit backfill materials or pit wall contact. It is expected that water quality in the bedrock aquifer and alluvial aquifer downgradient of the Yellow Pine pit ore body and at depths below shallow wells, is already impacted by spatially extensive mineralization and alteration in the area as well as legacy facilities.	WTR	The SDEIS describes water quality conditions as similar or improved compared to baseline conditions except for the case of the Hangar Flats and Yellow Pine pit backfills that have the potential to increase analyte concentrations in groundwater. The SDEIS indicates that potential groundwater effects would be limited to areas that have not been previously impacted, but that pore water outflow from the backfilled pit areas could affect areas that have not observed arsenic and antimony concentrations previously.
Alan Haslam (Vice President, Permitting, Perpetua)		31	11.0 Conservative Assumptions in the Site-Wide Water Chemistry Model Similar to Item 9, the discussion surrounding model sensitivity and uncertainty in Section 4.9.2.4 on pages 4-279 and 4-280 presents uncertainties and potentially non-conservative assumptions. This may lead to a biased review of the model because conservative assumptions used in the model are not	WTR	The SDEIS refers the reader to the Site-Wide Water Chemistry Model report with regard to the development and assumptions utilized by the geochemical model. The conservative assumption regarding acid-generation versus the lack of historical observations of acid-generation on site is captured in the discussion in SDEIS Section 3.9.4.2,

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Resources Idaho, Inc.)			<p>sufficiently presented. Presenting only non-conservative assumptions without discussion of conservative assumptions or further qualifying the non-conservative assumptions leads to a misunderstanding that predictions made by the SWWC model underpredict negative impacts and overpredict positive impacts.</p> <p>This is not the case. Many conservative assumptions were used during model development and use. The bullets on page 4-279 and page 4-280 should be further clarified with the caveats noted below for a fair and balanced discussion.</p> <ul style="list-style-type: none"> • “During the geochemical characterization program, three development rock samples were reported with paste pH less than 6. Although materials submitted for kinetic testing did not generate acidity during the duration of those tests (up to 197 weeks, far longer than industry-standard Humidity Cell Test durations), actual long-term conditions for the proposed mine facilities could vary the rate of sulfide oxidation along with the leachate pH and/or leached analyte concentrations.” [Caveat: However, site data show that acid generation has not occurred from historical mine waste despite exposure at surface for several decades. Circum-neutral to moderately alkaline baseline surface water and groundwater chemistry (and pit lake chemistry) also supports the assumption there has been no/limited acid generation from historical mine wastes.] 		i.e., "Historic waste rock and tailings have been left at the surface for decades (a duration more than 50 years longer than the proposed SGP mine life), with little evidence of acid rock drainage."
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		32	<p>“First-flush chemistry for contact water coming from development rock was not considered relevant to surface water quality predictions (SRK 2018a). This is deemed a non-conservative assumption. First-flush releases from the development rock material could cause short-term increases in downstream concentrations above and beyond what is currently predicted by the model.” [Caveat: However, it could be argued that the first flush chemistry will occur during operations, the majority of which will be managed as contact water and treated, therefore this will have minimal effect on in-stream concentrations. Furthermore, steady state chemistry is typically considered more representative for use in geochemical predictions (Maest and Kuipers, 2005; Price 1997). The initial flushing in humidity cells mobilizes oxidation products that formed prior to initiation of the test (i.e., they represent an accumulation of load derived at steady-state rates). This process represents a flushing effect in the lab but direct application of the humidity cell “first-flush” in the modeling is challenging since the load accumulation timeframe will be different in the field.</p> <p>Flushing effects can be accounted for using steady-state rates through accumulation of load during each time step. For example, the length of the timesteps of a pit lake model can vary from 1 year to 25 years. Flow always exists; however, the flushing load is inherently accounted for by releasing all load generated in each timestep in the estimated pit wall runoff volume.]</p>	WTR	The caveat regarding the first flush solute concentrations is captured in the discussion in SDEIS Section 3.9.4.2, i.e., "... because the first flush chemistries would be indicative of material leaching during the mine operating period, when leachate would be collected as contact water for water treatment or would be expected to dissipate in the near-term due to dilution and/or solubility controls."
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		33	<p>“Air temperature from the site was used to scale laboratory reaction rates to field conditions and could underestimate actual reaction rates and chemical releases from mined materials, and hence, surface water quality impacts.” [Caveat: However, during colder months of the year, actual reaction rates and chemical releases from mined materials could be overpredicted. The most practical approach is to use the average temperature value and recognize there is a potential for constituents to be seasonally higher or lower than predicted. Based on the sensitivity analysis, concentrations are higher for the higher temperature scenario; however, the difference is not significant enough to change the overall conclusions.]</p>	WTR	No revision made. Further discussion of the sensitivity of model predictions to scaling are provided in the text below the text referenced by the comment.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		34	<p>“Model-predicted concentrations generated by the SWWC Model are for the dissolved fraction only and may underpredict concentration levels for constituents such as mercury that have been shown to occur in particulate form.” [Caveat: However, surface water runoff will be managed during operations and a geosynthetic cover would be placed on the facilities at closure and overlain by an inert soil/rock layer and growth media and revegetated. These controls will limit the potential for particulates to contribute to constituent load in the surface water system.]</p>	WTR	Text has been added to reflect controls to limit particulate contributions to the surface water system.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		35	<p>"This is typically achieved by pumping from wells installed around the pit or sumps within the pit. " Both are typically needed. Please replace "or" with "and".</p>	WTR	Edit has been made.

Resources Idaho, Inc.)					
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		36	"Note that the SGP might still alter streamflow conditions (including access roads, utilities, and off-site facilities) outside the analysis area; however, such alterations are expected to be minor based on regulatory requirements for these alterations and the application of best management practices. " Changes in streamflow conditions would be limited to a change in the hydraulics at road crossing culverts only. No streamflow depletions would occur. Please consider deleting this sentence.	WTR	No revision made. The analysis reflects the potential for streamflow modifications which could occur as a result of the Project both on-site and off-site.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		37	"Low elevation snowpack usually melts quickly during the spring, but high elevation snow pact can persist into June or later " Please replace "snow pact" with "snowpack".	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		38	"The creek flows in the direction of, and then adjacent to, Stibnite Road (CR 50- 412) in a channel around the Bradley Northwest mine dump complex, disappears and then reemerges among historical mine development rock piles, and flows through a culvert before entering the East Fork SFSR. " Please update in the FEIS to reflect ASAOC diversion, which has the same surface course and outfall but eliminates it subbing out in the dump. Also, Hennessy Creek flows through 2 culverts before entering East Fork SFSR. Please replace "a culvert" with "two culverts".	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		39	"These values represent about 20 percent of the estimated annual precipitation for the SGP area , which is equal to 32.19 inches " Please define if "annual precipitation" is the MAP or the valley precipitation.	WTR	Clarification that the 32.19 inches pertains to the analysis area added to the text.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		40	Section 3 describes existing conditions. For Figure 3.8-3, please delete information related to modeling and action alternatives.	WTR	No revision made. This figure is utilized both for the baseline and effects analysis.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		41	In Table 3.8-5, please add significant digits to the numbers for YP-SR-6 (8.00), YP-T- 11 (3.30), YP-T-40 (0.80 and 2.80), YP-T-43 (49.00), and YP-T-48 (1.0) for consistency	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		42	"Mean discharge measured at the sites ranged from 0.0023 cfs at YP-AS-7 in the Meadow Creek drainage to 0.25 cfs at YP-SEBS-2 in the East Fork SFSR drainage. " YP-SEBS-2 is the re-emergence of Midnight Creek and should not be included as a seep or spring. Please replace "0.25 cfs at YP-SEBS-2 in the East Fork SFSR drainage" with "0.21 cfs at YP-S-10 in the Meadow Creek drainage"	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		43	In Table 3.8-6, please add significant digits to the numbers for YP-AS-4 (0.30 and 0.10) for consistency	WTR	Edit has been made.

Resources Idaho, Inc.)					
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		52	In footnotes, may want to clarify that UTM is in meters, as this may not widely known to the public.	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		53	"Figure 3.8-10 shows water table elevation contours for the analysis area computed by the groundwater model calibrated to water levels " Model also calibrated to streamflow yield. Please edit this sentence to say "...groundwater model calibrated to water levels and streamflow yield. "	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		54	"Overall, the results reported by the investigations (from 1989 to 2013) for the alluvial groundwater system indicate hydraulic conductivity ranging from 1 to 100 feet/day, with an average of approximately 10 feet/day " Please clarify if this is geometric mean.	WTR	No revision made. Text is appropriate as stated.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		55	"A long-term pumping test has not been completed in the deeper bedrock portions of the Idaho Batholith rocks in the Analysis Area as zones of groundwater inflow at depth sufficient to sustain a multi-day constant rate test have not been typically encountered in drillholes " - Consider revising: This description discounts the Hangar Flats pumping test. That hole was drilled to the specific purpose of testing deeper bedrock in the IB and it could not because there was no water. "not typically encountered" understates this.	WTR	The text has been revised per the results of the Hangar Flats and Yellow Pine pit area bedrock drilling.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		56	"Anticipated project groundwater supply areas would be in the vicinity of Hangar Flats pit area south of the currently authorized points of diversion (77-7141 and 77-7285) plus in the vicinity of the Yellow Pine pit " - Please clarify that these are industrial supply wells - the future worker housing will have its own well near that facility, along EFSF above MC	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		57	"The supply well locations represented on Figure 3.8-12 are preliminary in that specific locations for have not been finalized and will depend on engineering site evaluations to finalize well designs. " Missing the word "wells" between "for...have".	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		58	"There would also be groundwater production from a well located near the worker housing facility. " Should also be mentioned above. Also the reader would benefit from some explanation as to the distinction between industrial supply, dewatering, and dual-use wells.	WTR	No revision made. Text is appropriate as stated.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		59	"Under the No Action Alternative, there would be no large-scale mine operations by Perpetua, and water resources would continue to be impacted by currently permitted Perpetua drilling activities for exploration " . - Stating that water resources would be "impacted" by exploration drilling activities is misleading and alludes to negative impacts. Activities approved by the exploration drilling EA assume a finding of no significant impact. Also, this passage does not acknowledge that these uses would occur in	WTR	Edit has been made.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Resources Idaho, Inc.)			accordance with PRII's existing water rights. Please revise this to: "Under the No Action Alternative, MMP would not proceed and Perpetua Resources would not obtain a permit to acquire additional water rights. Perpetua Resources could continue to conduct approved exploration drilling activities and exercise their current water rights." This appropriately queues up the minimal impacts that follow.		
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		60	"Phase 1 of this agreement includes...This work is planned to occur between 2022 and 2024. " - The information in this passage is provided elsewhere, is more pertinent to water quality than quantity, and restating here is unnecessary and risks inconsistency with other locations in the document. Suggest replacing with a reference to the description of ASAOC activities in Section 1.3 and maintaining the last sentence, "These activities are not. "	WTR	No revision made. The text is necessary to establish the No Action effect on water quantity.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		61	"The SWWB evaluates operational consumptive use (e.g., mill water supply, dust control), TSF water volumes, and contact water volumes generated over the span of the project from construction through closure (Figure 4.8-2). " - There is no mention of water treatment here. Suggest it is applicable in the context of water quantity through storage of contact water and treatment capacity.	WTR	The text has been revised to add "... for contact water storage and water treatment capacity designs" to the end of the sentence.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		62	"The SHSM also forecasts the groundwater drawdown, and effects on groundwater discharge to surface water and the West End pit lake recharge".	WTR	The text has been revised to read (comma added) "... groundwater discharge to surface water, and pit lake recharge ..."
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		63	"Both the SWWB and SHSM provide input to the water chemistry and water temperature models described in the companion SGP Water Quality Specialist Report (Forest Service 2022f)." This sentence is inapplicable to a Water Quantity section. Suggest removing.	WTR	No revision made. Text is appropriate as stated.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		64	"Properties of the East Fork SFSR tunnel design include: " - Please include mention of the fishway for completeness. It is a very substantial element of the EFSFSR tunnel.	WTR	Text revised to read "Consistent with managing water and use of a fishway, properties of the East Fork SFSR ..."
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		65	" rock-cut, concrete-lined tunnel 15 feet wide by 15 feet high," - Please correct: Shotcrete and concrete are not the same product; the EFSFSR tunnel will be lined with shotcrete, steel sets, and rock bolts in various measures depending on local rock quality, but NOT concrete	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		66	For Fiddle Creek row, "pipeline" should be replaced with "culvert"	WTR	Edit has been made.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		67	For Meadow Creek row: Meadow Creek also has low flow pipes during operations and into closure. It would be good to highlight because these mitigate stream temps and also it is mentioned above. Please revise.	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		68	"The effects of stream diversions on water quantity would be moderate, long- term, and localized. " - Please clarify how this impact is quantified or strike; there is nothing in the preceding discussion that indicates impacts to water quantity due to stream diversions.	WTR	Text revised to indicate that effects of stream diversion on water quantity would be negligible.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		69	Footnote N/A should be not applicable, and it would be helpful to explain that they do not have embankments but rather are excavated in the ground.	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		70	"Capture of contact water for consumptive use would reduce the volume of runoff and hence, stream flow by between 0 and 1,600 gpm with typical average capture rates of approximately 800 gpm during the first 6 years of processing as the site water inventory is built (Figure 4.8-3) " Please correct, passage mixes volume with a rate. Moreover, these numbers are incorrect and conflate contact water storage with TSF inventory building for mill startup, and greatly overstate the rate and continuity of streamflow impact associated with contact water capture. Plus they presume a 1:1 ratio of contact water to streamflow. Contact water is generated from mine facilities that produce runoff at higher rates than wildlands. That contact water was destined for recharge or ET, not streamflow that same day. Please clarify (and correct) the source of the flowrates.	WTR	The capture rates are per the water balance figure from the Water Management Plan. The statement indicating the correlation with stream flow has been removed.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		71	"Contact water that is not used consumptively would be routed to the water treatment plant to achieve a water chemistry suitable for discharge to surface water in accordance with Idaho IPDES permit requirements " - For completeness, water treatment and discharge rates should be noted here as an offset to the depletion noted in the contact water storage.	WTR	Text added "During these times, water treatment and discharge would partially or fully offset effects of contact water capture and storage on stream flow."
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		72	"In addition, while much of the East Fork SFSR is not below the local water table, some sections of the East Fork SFSR tunnel may periodically..."	WTR	No revision made. Text is appropriate as stated.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		73	"Water demands for ore processing would necessitate the installation of production wells and a surface water diversion from the East Fork SFSR, in addition to the dewatering system ". Please insert " contact water that includes the dewatering system" to clarify this sentence.	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua		74	"A detailed explanation of the conceptual hydrogeologic model, modeling approach and setup, steady-state and transient calibration..." - There is no "steady-state" calibration. Delete "steady-state"	WTR	Edit has been made.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Resources Idaho, Inc.)					
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		75	"No flow conditions..." - Add hyphen to no-flow to clarify appropriate meaning.	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		76	"Model calibration was accomplished using a process that included simulation of pre-mining steady state conditions and then transient conditions associated with the pumping tests." - Delete 'steady state'.	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		77	"...the hydraulic conductivity values to vary within the range of the aquifer test results for each unit." - Should also discuss that the MWB and SHSM were calibrated together. MWB included soil storage parameters (thickness, FC, WP).	WTR	No revision made. Text is appropriate as stated. SDEIS Section 4.8.2.2 provides information regarding the model calibration and selection of the hydraulic conductivity values utilized for model predictions.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		78	"...dewatering requirements to achieve dry mining conditions ..." - Dewatering is also important/more important for pit wall stability. Please revise.	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		79	Paragraphs 2 and 3 are repeated paragraphs from above. Please revise.	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		80	"Predicted dewatering rates and underdrain flows were combined with estimated volumes of mine-impacted waters from the SWWB to forecast the volume requirements for water treatment during operations and closure." - Incorrect. Underdrain water was assumed to be discharged without requiring treatment in the SWWB and SHSM models, based on predicted water quality assumed to likely to meet IPDES permit limits. Please revise.	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		81	"These volumes ranged from 2,000 gpm during the years of highest dewatering production down to 150 gpm ..." - Please clarify that "these volumes" refers to the water treatment volumes. Also, predicted treatment volume goes to zero gpm many months, not just down to 150 gpm.	WTR	The text has been revised to state that the minimum water treatment volume is zero rather than 150 gpm.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		82	"...range between the 5th and 95th percentiles of meteoric inputs ..." - The reported 5th-95th stats are on the outputs (treatment, storage volume, etc.) not the meteoric inputs. Please revise.	WTR	Edit has been made.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Resources Idaho, Inc.)					
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		83	"Predicted flows averaging approximately 1,400 gpm would reduce to approximately 1,200 gpm in response ..." Please clarify what these flows represent (e.g. average, max, annual)	WTR	The text has been revised to indicate that this difference represents the maximum difference in flows.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		84	"Groundwater levels away from the pit dewatering focus areas would observe measurable reductions in water levels constituting a minor or moderate effect while groundwater levels in the dewatering focus areas would observe drawdown of several hundred feet, constituting a major effect " - Please provide context for the reader here as to how these assessments are made. Active dewatering only lasts single-digit years and rebound similarly only a few years after max extent at YP and HF.	WTR	No revision made. Text is appropriate as stated.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		85	"Away from the TSF area, groundwater levels would rebound during the post closure period, with most recovery occurring within 3 years following the cessation of groundwater pumping ..." - Please clarify that pumping of YP and HF stops long before overall site closure; this sentence alludes to it occurring in post- closure.	WTR	Revision made to remove "during the post-closure period."
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		86	Please provide context for these figures in light of their titles; The apparent persistent and large drawdowns at YP and HF are entirely due to topographic changes not lingering effects of dewatering. Please revise.	WTR	The text has been revised to describe topographic changes.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		87	"Impacts to Groundwater Dependent Ecosystems " Section 4.8 Surface and Groundwater Quantity and Section 4.11 Wetlands and Riparian Resources both use groundwater drawdown as an important part of impact characterization. Section 4.8 refers to streams and wetlands and groundwater dependent ecosystems (GDEs) (Impacts to Groundwater Dependent Ecosystems) and Section 4.11 (Alteration of Wetlands and Riparian Areas Due to Changes in Water Balance) does not use this terminology at all, and only addresses wetlands, and not streams. The part of Section 4.11 that addresses groundwater drawdown effects on wetlands does not specifically reference Impacts to Groundwater Dependent Ecosystems. As a result, there are two sections that analyze the same thing, but are independent and present things differently. The analysis of groundwater dependent resources should be taken out of Section 4.8 and integrated into 4.11, and the terminology made consistent.	WTR	The analysis of groundwater dependent ecosystems has been retained in Section 4.8 because that effect is tied to the groundwater drawdown described in that section. Text has been added to Section 4.11 to reference the reader to the discussion in Section 4.8 and to standardize language.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		88	"This groundwater discharge may emanate from a local system or from the regional groundwater system " - There is no evidence of any "regional" GW system at the site. The term should be removed globally from the SDEIS document.	WTR	No revision made. Text is appropriate as stated. Regional groundwater refers to the deeper groundwater system that would be targeted via mine dewatering versus localized perched zones of subsurface water.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		89	"Potential impacts to seeps, springs, and GDEs were evaluated by comparing surface water locations to the predicted ten-foot drawdown contour resulting from mine dewatering and water production." - Additional clarification will be helpful here. With the statements above that, "For this impact analysis, the area that is predicted to experience a change in groundwater elevation of ten feet or more is used for quantification and comparison of project effects and baseline conditions. ", it should be clarified how the 10 ft contour is being used to evaluate impacts to the GDEs. Moreover, many of the GDEs shown on	WTR	The uncertainties in predicting groundwater drawdown effects on groundwater dependent ecosystems are described in Section 4.8.2.2. These uncertainties are associated with each site-specific relationship between a GDE and local groundwater. These site-specific relationships typically cannot be determined until the groundwater aquifer is affected by large scale pumping for a period of time. Therefore, they are not currently known and not represented on Figure 4.8-10 which presents the conservative extent for GDE effects. The figure also depicts

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Resources Idaho, Inc.)			Figure 4.8-10 are beneath the footprint of the TSF, which should be disclosed to put perspective on the impact; many of these wetlands and streams (GDE's) are "directly" impacted as they will be lost during construction, and so to point them out as being "indirectly" impacted due to groundwater lowering is misleading. Only GDEs that are not directly lost (and thus potentially impacted by groundwater lowering) should be presented. Please revise.		the stream locations that would be within the areas of surface disturbance so that these areas can be differentiated from locations with groundwater drawdown outside the disturbance footprint.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		90	"This rate would be for combined groundwater and surface water diversion in addition to existing water rights." Suggest adding to the end of this sentence, "...including dewatering flows that are treated and discharged,"	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		91	"Separate water rights applications would be submitted for each well" - These water rights applications have been submitted. Multiple references to pending applications in this document should be corrected.	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		92	"Stream diversion around mine facilities" - Please clarify how modifying the location of a stream will impact water quantity.	WTR	Text has been added to clarify that diversions affect the path of surface water flows.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		93	"These activities have the potential to modify the location and flow rate of stream flows in the analysis are a." - This should be "and/or" if stream diversions must be included.	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		94	This figure is misleading because the discussion above states essentially that drawdown of less than 10 ft is uncertain with the regional scale model and seasonal fluctuations. Here, there is no information aside from the 10 ft contour. The reader is left to guess if seeps/springs within the contour are affected, even though the model can't predict at that resolution. Also, it should show/explain that many GDE's shown here are directly lost to construction (direct impact) and should not be also shown as indirectly impacted, because they will not longer exist. Please revise discussion.	WTR	SDEIS Section 4.8.2.2 text acknowledges the uncertainties between comparing surface water locations to the 10-foot groundwater contour. The uncertainties in predicting groundwater drawdown effects on groundwater dependent ecosystems are described in Section 4.8.2.2. These uncertainties are associated with each site-specific relationship between a GDE and local groundwater. These site-specific relationships typically cannot be determined until the groundwater aquifer is affected by large scale pumping for a period of time. Therefore, they are not currently known and not represented on Figure 4.8-10 which presents the conservative extent for GDE effects. The figure also depicts the stream locations that would be within the areas of surface disturbance so that these areas can be differentiated from locations with groundwater drawdown outside the disturbance footprint.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		95	"The model predicts reductions in Meadow Creek flows between the TSF and Hangar Flats pit compared to baseline flows of up to approximately 40 percent during low flow periods...during the construction and operational period for the SGP ". This statement is misleading as presented, does not provide numerical flow rates provided for similar statements below, is provided without context as to the temporal range of this potential impact, and separated by 2 additional sentences from a design feature that is intended to ameliorate its impact. Please move the following passage: "However, baseflow depletion is largely offset by the addition of treated water in this portion of Meadow Creek via an IPDES permitted outfall. This offset is anticipated to be substantially effective because the predicted impact is primarily associated with dewatering of the Hangar Flats pit. " to follow it directly. Also, please provide	WTR	Edit has been made.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			the reader with numerical flow rates (as with other examples below) as well as temporal context for this impact, which begins in year 5 and ends in year 6. As presented, the reader is left to understand this as an impact that occurs from construction through operations.		
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		96	Please verify that the streamflow impacts presented in Table 4.8-4 are aligned with those presented in Section 4.12.	WTR	The streamflow changes described in Table 4.8-4 were utilized in the analysis of Fish Habitat in Section 4.12.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		97	For the Station <i>East Fork SFSR below Sugar Creek (13311500)</i> - The location of this station is beyond the model domain and therefore point of comparison would be the same as 13311250. The reference to gauge 13311500 should be deleted.	WTR	USGS Gauge 13311250 is located above the confluence of East Fork SFSR and Sugar Creek. USGS Gauge 13311500 is located downstream of the confluence and is used for comparison of baseline conditions to model predictions downstream of Sugar Creek.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		98	"Flow reductions are predicted during the project's operational period with the largest flow reductions (i.e., on the order of 40 percent) occurring during Mine Years 4 through 8 as Hanger Flats pit is being dewatered." - Please provide the reader appropriate clarification here: the phrase "during...operational pd" makes it sound like the reductions are longer-term than they really are. There is only about 18 months of mining HF below the GWT.	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		99	"Flows recover toward the No Action Alternative condition following the cessation of Hanger Flats dewatering and are near equivalent to the No Action Alternative conditions by Mine Year 12. " - Please correct: HF dewatering ends before 8, and by EOY 8 groundwater there is actually rebounded.	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		100	"...minimum baseflows based on comparison of model results to the existing conditions model for the action alternatives would be approximately 6.6 cfs compared to 8.9 cfs (26 percent reduction) for the No Action Alternative attributable to the diversion and capture (contact water) of surface water as well as mine dewatering. Downstream of the Yellow Pine pit area prior to the confluence with Sugar Creek, minimum baseflows for the action alternatives are predicted to be 7.9 cfs compared to 11.3 cfs under the No Action (30 percent reduction) under the proposed water management scenario and its associated water balance " - Please provide additional context for the reader. Putting it in later sentences is misleading, and this ignores the treated water discharge.	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		101	Referenced Figure 4.8-15 does not include Sugar Creek. Please add.	WTR	Figure title corrected.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		102	"During the post-closure period when the West End pit lake is forming, predicted Sugar Creek flows decrease by up to 9 percent primarily. " - Please clarify what part of the flow regime / how long and often.	WTR	Edit has been made.
Alan Haslam (Vice President,		103	"Typical rates of surface water diversion during the build-up of project water inventory would be approximately 4 cfs ". - The reader may not be familiar with what "buildup of project water inventory"	WTR	Edit has been made.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Permitting, Perpetua Resources Idaho, Inc.)			means. Moreover, it is misused elsewhere to refer to several years of mine ops. Please clarify its definition here.		
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		104	"and up to 8.2 cfs of new non-domestic, commercial, municipal, and industrial uses. This would allow authorization of up to 8.2 cfs of new non-domestic, commercial, municipal and industrial water rights to which Water Right 77-14190 would be subordinate. " - the term non-DCMI can be used here. Also, please clarify that the PRII water right applications are for industrial and domestic uses and thus the EFSFSR minimum streamflow right is subordinate to it.	WTR	No revision made. Text is appropriate as stated.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		105	"would be insufficient " should be "would be sufficient"	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		106	"Instream rights on the SFSR are subordinate to 20.6 cfs; maximum diversions proposed by Perpetua from all sources and uses would be 9.68 cfs, within the allowance of the SFSR instream rights. " For clarity and accuracy, this sentence should say, "Instream rights on the SFSR are subordinate to all future DCMI uses and up 20.6 cfs for future non-DCMI uses; maximum diversions proposed by Perpetua are within the allowance of the SFSR instream rights."	WTR	No revision made. Text is appropriate as stated.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		107	"The current seasonal low baseflow in the Salmon River is approximately 4,150 cfs near Shoup gage. " - Incorrect. Average flow at Shoup gage in late August and early September is 1400 cfs.	WTR	Revision made. The seasonal low baseflow suggested by the comment is consistent with the information in the Order regarding the Consolidated Subcase No. 75-13316 Wild & Scenic Rivers Act Claims.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		108	"For the Yellow Pine pit dewatering, peak pumping rates associated with the sensitivity analysis ranged up to approximately 2,000 gpm compared to the model predicted rate of approximately 650 gpm. For Hangar Flats pit and West End pit dewatering, the sensitivity analysis peak pumping rate ranged up to approximately 2,400 gpm compared to a predicted value of approximately 1,500 gpm, " - It should be stated that the 10x sim for layer 3, 4, 5 was poorly calibrated and this is an overestimate. Additional details are in the attached comment letter.	WTR	This section has been revised to incorporate limited test data collected from the Hangar Flats and Yellow Pine pit areas.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		109	"Therefore, surface water flow rates would be within 0.5 cfs of those predicted by the model, representing the difference between predicted surface flow rate reductions and removing the rate of forecasted withdrawal from the intake above the EFSFSR tunnel, which would no longer be needed." - This should have a reference and its accuracy validated. BC did not conduct this analysis.	WTR	The difference in surface water flow is based on the sensitivity range of mine dewatering rates. If mine dewatering rates are lower than projected by SHSM and water supplied from surface water, the magnitude of that surface water supply would be as described.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		110	"Predictive sensitivity to various possible degrees of hydraulic transmissivity of the fault zones, only one of which has been explicitly represented in the model; " - This could be more clearly stated as: "Predictive sensitivity to various possible degrees of hydraulic transmissivity of the fault zones, of which the major fault zone has been explicitly represented;...".	WTR	No revision made. Text is appropriate as stated.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		111	"Putative inability to directly observe the effects of long-term hydraulic stresses on the bedrock aquifer as attempted deep bedrock pumping tests have not been completed due to the inability to sustain groundwater production from a pumping well." - This statement does not consider the current aquifer	WTR	This section has been revised to incorporate test data collected from the Hangar Flats and Yellow Pine pit areas.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Perpetua Resources Idaho, Inc.)			testing program and will need to be struck from the final EIS. Moreover, the inability to observe effects is the result of the pumping test. And that result is more correctly characterized as no effect observed from pumping stress (drawdown) induced at the pumping well indicates extremely low or no hydraulic connection in deep bedrock.		
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		112	Here and globally where applicable, descriptions of the No Action Alternative should acknowledge ASAOC activities. Please revise.	WTR	No revision made. Text is appropriate as stated.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		113	"Impacts to surface stream flow rates from the SGP would be irretrievable commitments of these resources." - This statement seems contradictory to the rest of the preceding paragraph which calls out no permanent impacts. Please revise.	WTR	Irretrievable impacts are not necessarily permanent, they are Project effects that are lost for a period of time but are restored at some point in the reasonably near future.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		114	"These would be irreversible commitments of these resources." - Please clarify how the rerouting of a stream is an irreversible commitment of a resource.	WTR	The re-routing on the stream permanently modifies the location of the surface water flow.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		115	"...the groundwater levels in the backfills are expected to reach approximate baseline elevations as influenced by the revised groundwater flow in the backfills. These would be irreversible commitments of the groundwater system in these locations." - Please clarify how this is characterized as an irreversible commitment.	WTR	The volume of groundwater inundating the pit backfill is greater than the volume of groundwater within native material (i.e., consolidated bedrock) within the pit shell. This effect has been reclassified as irretrievable rather than irreversible, because groundwater levels are expected to recover over time.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		116	"The West End pit lake would be situated primarily in bedrock and therefore would not receive substantial groundwater inflows." - Being situated primarily in bedrock could also be said of the Yellow Pine pit. A more substantial description would be helpful here.	WTR	No revision made. Text is appropriate as stated.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		117	"Implementation of the SGP would result in long-term impacts to surface water quantity at the SGP through groundwater withdrawal and stream diversions." - Here and elsewhere in this Section, please provide clarifying information as to how stream diversions are an impact to water quantity.	WTR	"Long-term" is defined in Section 4.1. While there are quantitative predictions for effects on surface water quantity that vary by location, they all fall into the long-term category as defined.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		118	"Saturated thickness of alluvial deposits and their groundwater transmissive properties would remain similar to baseline conditions except in the three open pit areas where the alluvial deposits were removed during the mining period." Unclear if its stating otherwise, but backfills would be thicker and higher-K than the alluvium, since they replace both alluvium and bedrock. Please clarify.	WTR	Text added to note that pit backfill would be high permeability.
Alan Haslam (Vice President, Permitting,		119	Table 2-3 includes no discussion of backfill covers or the TSF cover as a proponent design feature. Please add.	WTR	Edit has been made.

Perpetua Resources Idaho, Inc.)					
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		120	"The Meadow Creek Fault Zone acts as an aquitard to bedrock flow based on observations of surface water expressions above the fault zone gouge outcrops and artesian conditions observed in drillholes in its vicinity where it passes between the Yellow Pine pit and West End areas. " - The MCFZ is identified in as the major structure of the area here, however, a source of uncertainty in Section 4.8 is stated as "Predictive sensitivity to various possible degrees of hydraulic transmissivity of the fault zones, only one of which has been explicitly represented in the model". This tone of this statement should be carried over to Section 4.8 page 4-177.	WTR	No revision made. Text is appropriate as stated.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		121	"Table 6-5 provides the maximum instantaneous flow predicted to occur for various return periods from a 1.5-year event up to a 500-year event ". Table 6-5 provides flows only up to a 100-year event, not 500 years as indicated here.	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		122	"Water Right 77-14190 is subordinate to future non-domestic, commercial, municipal, and industrial uses and future non-domestic, commercial, municipal, and industrial development up to 8.2 cfs. " - This repeats non-DCMI twice. The statement should read, "Water Right 77-14190 is subordinate to future non- domestic, commercial, municipal, and industrial uses and future non-domestic, commercial, municipal, and industrial development up to 8.2 cfs".	WTR	No revision made. Text is consistent with the description of subordination for Water Right 77-14190.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		123	"They also are subordinated to specified quantities of future beneficial use rights. Additional detailed information regarding these two water rights can be found in Water Right Reports (referenced by water right number) available on the IDWR website... " - This water right should be treated in more detail and highlight the allowable water right development under the WR and the subordination clause. This is a pretty critical understanding for water right application at the SGP.	WTR	No revision made. The EIS does not attempt to impart any interpretation of water rights applications submitted to IDWR.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		124	"Model calibration was accomplished using a process that included simulation of pre-mining steady state condition s..." - This is incorrect - reword to remove steady state and include other calibration parameters.	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		125	For parameters in Table 3.9-1 that are indicated as EPA Secondary Drinking Water Standards (Al, Fe, Fl, Mn, SO3, TDS) please note/indicate that these standards are not enforceable or directly applicable for environmental waters.	WTR	Revision not accepted. The identification of the EPA Secondary Drinking Water Standard supplies the context for these criteria.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		126	"table-reported standard values utilize the 12 ng/L (0.000012 mg/L) representing the lowest concentration adopted as a standard " - Please clarify if the 12 ng/L value is for MeHg or just Hg.	WTR	Text added to reflect that the 12 ng/L standard applies for Hg.
Alan Haslam (Vice President, Permitting,		127	"Antimony occurs as the mineral stibnite (Sb2As3) " - Please correct: Stibnite is Sb2S3. It is a sulfide and has no arsenic in its formula.	WTR	Revision made.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Perpetua Resources Idaho, Inc.)					
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		128	"The primary intrusive and metasedimentary rock types at the mine site include alaskite, granodiorite (i.e., quartz monzonite), diorite, rhyolite, calc-silicate, carbonates (e.g., dolomite and limestone)... " - Limestone is not a metamorphic rock, please revise to marble (metamorphosed limestone).	WTR	Revision made. "(e.g., dolomite and limestone)" removed from the text.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		129	"Results from the multi-element testing show that arsenic, mercury, sulfur, and antimony are enriched... " - Please clarify by defining "enriched" (enriched vs. average crustal abundance). Without context, this sentence implies a high concentration of Hg when there really isn't.	WTR	Revision made. "compared to crustal abundance" added to text.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		130	TSF Embankment column, Height row - "state" should be "stage"	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		131	"...Net Potential Ratio (NPR) " - should be "Neutralizing", not "Net"	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		132	"Effluent concentrations of aluminum, antimony, arsenic, and mercury frequently exceeded their respective most stringent water quality criteria ... " - It should be clarified that this is the TEST effluent, not a direct prediction of contact water quality	WTR	"Effluent concentrations" replaced with "Test effluent concentrations."
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		133	"Decant solution chemistry for five samples of synthetic tailings materials... " - Please replace "synthetic" with "pilot" or "metallurgical pilot program" These tailings were from a full-flowsheet pilot test, not synthesized after the fact / or to match predictions and solely for environmental testing as is often done in water treatment piloting.	WTR	"synthetic" replaced with "metallurgical pilot program".
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		134	"A few constituents are mobile under these neutral to alkaline pH conditions, including aluminum, antimony, arsenic, manganese, and mercury, which were frequently leached at concentrations above the strictest potentially applicable surface water quality standard." - Please clarify this is from samples, and is NOT a direct prediction of leachate at field scale. Hg for example is predicted to be below WQS.	WTR	This section describes the humidity cell test results. The field scale leaching predictions are described in Section 4.9.2.2.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		135	In table 3.9-8, please clarify for the reader that the reported values are the test leachate values and not a direct prediction of Project mine-impacted water quality.	WTR	This section describes the humidity cell test results. The field scale leaching predictions are described in Section 4.9.2.2.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Resources Idaho, Inc.)					
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		136	"HCT analytical results were utilized in developing modeling source terms for the water chemistry predictions. In the development of source terms, the initial flushes from the HCTs were not utilized (SRK 2018) because the first flush chemistries would be indicative of material leaching during the mine operating period, when leachate would be collected as contact water for water treatment or would be expected to dissipate in the near-term due to dilution and/or solubility controls." - Additional clarification of this point that supports the use of steady state conditions for development of source terms would provide a more complete justification of source term development. Suggested addition is "Steady state chemistry is typically considered more representative for use in geochemical predictions (Maest and Kuipers, 2005; Price 1997). The initial flushing in humidity cells mobilizes oxidation products that formed prior to initiation of the test (i.e., they represent an accumulation of load derived at steady-state rates)". Please reference the comment letter for additional detail.	WTR	No further clarification necessary.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		137	"The water quality of nearby seeps associated with the Bradley tailings, SODA, and Keyway Dam also was elevated in metals, an indication that historical mining features are impacting the alluvial and bedrock aquifers." - Please support this assertion with evidence or remove. Nothing described in this sentence should have any effect on bedrock as these are mine waste features sitting on top of alluvium in the valley bottom where gradients are generally vertically upward and down-valley, not into bedrock.	WTR	The mention of bedrock aquifers has been removed.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		138	"Natural springs and seeps also occur where bedrock faults and fractures intersect the ground surface". - Please provide a source for this statement or remove. It would be more general and more accurate to say "Natural springs and seeps occur at other locations where the local water table intersects the ground surface..."	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		139	"Similarly, in the East Fork SFSR drainage, arsenic and antimony concentrations in seeps and springs are elevated below the Yellow Pine pit and Northwest Bradley waste rock dump, suggesting that these historical mine facilities are responsible for elevated concentrations of arsenic and antimony in discharging groundwater" - Please provide a more recent citation (than URS 2000b) to qualify this statement. Identifying the mentioned springs below YPP would be helpful as well.	WTR	Citation to HDR 2017f added.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		140	"The low sulfate and TDS concentrations also could point to a lack of mineralized deposits and historical mining-related impacts in the Fiddle Creek drainage, and different lithologies in the catchment area, specifically calcareous rock formations" - Please clarify the mentioned calcareous rock formations in the Fiddle drainage.	WTR	"specifically calcareous rock formations" removed from sentence.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		141	Please clarify the purpose of this table. It seems to imply a bias on the part of one of the sampling entities. But since the % differences are absolute values, the reader has to look more closely to see which entity reported higher values. Please validate calculations as well. It is also worth noting that the USGS specifically samples at highest flow events, so their Hg numbers are expected to be elevated relative to PRII, which normally samples in mid-May per their quarterly sampling schedule.	WTR	The table is intended to summarize the available USGS and Perpetua surface water data. The % difference columns have been removed from the table and a footnote added to reflect sample collection times.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		142	"...attributable to the dissolution of soluble salts and the flushing of water concentrated by evaporation." - Evapoconcentration is not likely the cause as the water in question is held in pore space below the root zone (and there is little vegetation on many of the piles in any event)...It is more likely the long residence time of GW in the waste piles all summer/fall/winter, leading to higher concentration, followed by it being displaced by incoming melt in spring.	WTR	"and the flushing of water concentrated by evaporation" has been removed from the text.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		143	"The range of observed MeHg values varied between a minimum of <0.1 ng/L (all sites) to a maximum of 0.64 ng/L (Sugar Creek). Mean MeHg values (calculated using the method detection limit for non-detect results) were at or just above the 0.1 ng/L detection limit." - Including mean MeHg values ("average in table 3.9-12) is not likely helpful to the reader, and it isn't needed to understand the results. Moreover, it does not seem reasonable to assign the MDL to all non-detect samples when doing this calculation (see EPA Unified Guidance). This section could simply specify the number of samples that were non-detect and remove the averages from Table 3.9-12.	WTR	Revision not accepted. Indicating the average condition for the sample locations is appropriate for describing the data set.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		144	"Despite these relatively high concentrations, the mine site seeps do not appear to significantly influence surface water MeHg levels (e.g., loading), either due to the low seep flow rates compared to surface water flows". - Incomplete sentence. Please clarify.	WTR	"either" removed from the sentence.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		145	"Based on data from the 2016 Integrated Report ..." - Elsewhere the 2020 report is cited. Please check this reference.	WTR	Reference updated.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		146	"These analytical method detection limits are greater than the strictest potentially applied water quality standard and it is uncertain whether the pit lake water meets that standard." - It could be inferred, if the stream above and below meets the standard, the lake does as well given the short residence time and fully-mixed conditions.	WTR	The current narrative is appropriate for the available data. No inference is required for this description.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		147	"Data presented in this table show that average concentrations of pH, aluminum, arsenic, iron, manganese, and antimony exceed the groundwater quality standards." - Identification of secondary GW quality standards is relegated to a footnote in Table 3.9-18. Please clarify what secondary standards are here when introducing this table, and their lack of relevance to ambient water.	WTR	The application of standards is discernible from the footnote.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		148	"whereas criteria for iron, aluminum, and manganese are based on secondary standards established to protect aesthetic and cosmetic qualities of drinking water" - It would be helpful to the reader to move this content to the introduction of Table 3.9-18. The current introduction lists apparent violations of standards that aren't really standards at all, and is thus misleading.	WTR	The identification and description of secondary standards is consistent with their regulatory application.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		149	"Surface water quality parameters (e.g., pH, temperature, major ions, TDS, metals, sediment content, and organic carbon" - Please clarify the significance of organic carbon as an indicator; a precursor to MeHg perhaps but it doesn't seem likely to be itself an indicator, or much influenced by the project (small amount in sanitary wastewater).	WTR	The relevance of organic carbon is described later in SDEIS Section 4.9.2.2.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		150	"...water quality predictions from modeling studies completed by Perpetua and their consultants for the SGP ..." - Please note and clarify for the reader that modeling was conducted and updated specifically for the 2021 MMP.	WTR	Revision made. "for the SGP" replaced with "for the 2021 MMP"

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		151	<p><i>"The hydrologic modeling is summarized in the companion SGP Water Quantity Specialist Report (Forest Service 2022e) and additional modeling details can be located in the modeling reports provided by Perpetua (Brown and Caldwell 2021a, 2021e, 2021i, SRK 2021a)." - In the reference list, SRK 2021a is listed as the Geochemical Characterization Report. This paragraph should cite the ModPRO2 SWWC Modeling Report (which should be added to the reference list. The SWWC report was included in the SDEIS supporting documents on the USFS website).</i></p> <p>General comment – the SRK reports are often referenced incorrectly throughout this section of the SDEIS:</p> <ul style="list-style-type: none"> Any references to the SWWC modeling should cite the Stibnite Gold Project ModPRO2 SWWC Modeling Report, October 2021 (not in the reference list, but IS in the SDEIS supporting documents) Any references to the SWWC model sensitivity analysis should cite the ModPRO2 SWWC Model Sensitivity Analysis Report, November 2021 (currently listed as SRK, 2021b in the reference list) Any references to the geochemical characterization should cite the Comprehensive Baseline Geochemical Characterization Report, November 2021 (currently listed as SRK, 2021a in the reference list). 	WTR	References to the SWWC model changed from "(SRK 2021a)" or "(SRK 2021)" to "(SRK 2021b)".
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		152	<p><i>"...testing of synthesized and legacy tailings samples." - As in Section 3.9, these are pilot plant tailings and not accurately characterized as "synthesized". That term is likely to lead to bias and the incorrect impression that the tailings samples were somehow not representative. Please revise.</i></p>	WTR	"synthetized" replaces with "metallurgical pilot program".
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		153	<p><i>"The test cell HC-14 from the Phase I testing program was selected to represent PAG development rock and wall rock because this cell had the highest total sulfur and highest sulfate leaching rate, which corresponds to maximum sulfide oxidation and acid rock drainage potential." - It would be helpful to clarify for the reader here that none of the HCTs developed acidic conditions.</i></p> <p>Suggest adding context to the effect of: "Even though the material is technically classed as PAG based on an NPR<1.5, in reality this material is unlikely to be acid generating. None of the humidity cells (7 out of 25 of which were classed as PAG based on the static test results) generated acidic leachates despite continued testing of up to 184 weeks (significantly beyond the standard timeframe of testing). This is supported by: (i) the historical mining wastes, which have not generated acid despite being exposed at surface for several decades; and (ii) the circum-neutral to moderately alkaline groundwater and surface waters in the project area."</p>	WTR	Revision made with text added per comment.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		154	<p><i>"A site-wide water balance model was performed by Brown & Caldwell..." - This is incorrect; the SWWB model was prepared by Perpetua though it relied on BC's SHSM and MWB. Please revise and correct reference list.</i></p>	WTR	The final version submitted for the Site Wide Water Balance model was delivered as a Brown & Caldwell document.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		155	<p><i>4.9.1.4 Groundwater Chemistry Model - The title of this section (Groundwater Chemistry Model) is misleading. The geochemical modeling performed by SRK encompasses predictions of seepage and contact water chemistry from proposed mine facilities (e.g., TSF, TSF Buttress, Hangar Flats and Yellow Pine backfill) as well as the pit lake water quality predictions for the West End pit. The section would be more appropriately titled 'Mine Facility Water Chemistry Models'. Source terms from these facility models were used as inputs to the SWWC model to evaluate impacts to surface water. An evaluation of impacts to groundwater are limited to the TSF and TSF Buttress facility models. Please revise.</i></p>	WTR	Revision not accepted. The context for the groundwater geochemical modeling is described in the section.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		156	"...inundated backfill in the Yellow Pine pit, Hangar Flats pit, and Midnight pit..." - This is incorrect. The Midnight Pit backfill is unsaturated. Please revise.	WTR	The adjective "inundated" has been removed from the text.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		157	"...the TSF Buttress, pit lake s..." - Please correct "pit lakes" to be singular. The reference to plural pit lakes is found throughout the document and this change needs to be made globally.	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		158	"Ammonia concentrations in surface waters were not explicitly modeled..." - Suggest striking this passage. There are other parameters that were not modeled and more explanation is needed to explain what was modeled, what wasn't and why. This level of detail is beyond a summary level of information.	WTR	Revision not accepted. The discussion of ammonia is provided per comments received on the 2020 DEIS.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		159	"This removal is part of the planned Phase I scope for the ASAOC signed in 2021 with implementation anticipated in 2022 and 2024". - ASAOC activities are planned in 2023 as well. please correct.	WTR	"in 2022 and 2024" has been revised to "between 2022 and 2024".
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		160	"Soil sampling and analysis indicate that legacy mining wastes..." - To clarify, please add "and naturally occurring mineralization"	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		161	"The elevated antimony and arsenic concentrations in groundwater are unlikely to improve in the future under the No Action Alternative." - This is not consistent with the statement above that "there would also be a potential improvement in groundwater analyte concentrations" associated with the ASAOC activities. It would helpful to the reader to include a statement in here that says the ASAOC activities will result in some improvement in surface water and groundwater conditions, but that it is limited and not to the same degree as implementing the mine plan.	WTR	The sentence has been removed from the text to provide consistency with the prior statement.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		162	"As such, there would be no change to the existing condition of surface water quality related to off-site facilities." - Here or elsewhere, the No Action description should also state that vegetation restoration and plantings would not occur under No Action. The plantings proposed for the SGP include streams that will not be directly impacted by mining activities. Without the restoration plantings, the shade along these reaches would not increase as quickly.	WTR	Following the streamflow paragraph, text was added to state "Proposed stream restoration and revegetation activities would not occur and their effects on reduced sedimentation and stream temperature would not occur."
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		163	"Solute generated from mined materials are expected to be partially to substantively controlled by water management practices that are part of the SGP" - It is also worth mentioning that there are numerous engineering controls also being proposed (i.e., geosynthetic liners) that prevent solutes from being generated or entering the environment; a significant design feature added to the MMP. Please revise.	WTR	The use of geosynthetic liners is a component of the water management. The text has been revised to read "proposed water management practices and facility designs".

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		164	"In addition to solute mobilization, the temperatures of surface waters would be affected by the proposed project as it modifies the flow and shading characteristics of the mine area which affect stream temperatures." - please clarify that this is not a permanent condition by adding: '...during mine operations. Once pit watering stopped, groundwater levels and stream flows would increase and return to No Action levels. Shading characteristics would return to No Action conditions and improve over time as a result of the restoration plantings, vegetation monitoring, and adaptive management.'	WTR	The duration and nature of temperature effects is described in detail later in Section 4.9.2.2.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		165	"...consolidation water from the TSF (construction through closure which includes process water); " - Please correct, there is no consolidation water in construction as there is no processing and no tailings.	WTR	Revision made to reflect operations through closure.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		166	The header "Contact Water Pond Chemistry" should also mention contact water use, which is described within the subsection. Please revise.	WTR	Revision not accepted. Contact water use is described in SDEIS Section 4.8.2.2.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		167	For SODA pond, iron should not be listed as being above the strictest potentially applicable WQS. Please revise.	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		168	Inflow sources for Plant ponds should also include plant site runoff. Please revise.	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		169	For Plant ponds, selenium should not be listed as being above the strictest potentially applicable WQS. Please revise.	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		170	The final paragraph of p 4-189 describes trends that are not consistent with the dewatering chemistry provided in Appendix D of the SWWC report. Also, this level of detail is not consistent with a summary. Please revise.	WTR	Text revised per the SWWC report table in Appendix D6.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		171	"Predicted water chemistries for the stockpiles exhibited circum-neutral pH values with antimony concentrations (0.008 mg/L to 0.016 mg/L) and arsenic concentrations (0.069 mg/L to 0.25 mg/L), both above the strictest potentially applied water quality standards " - It is incorrect to say these values relate to predicted water chemistry for the stockpiles. These values relate to the ore stockpile HCT source terms and have not been scaled to field conditions. Please correct/clarify.	WTR	Revision made. "Predicted water chemistries for the stockpiles" revised to "HCT samples representative of stockpile material".

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		172	" <i>The residence time in the aquifer...</i> " - Rather than referring to the residence time in the aquifer, it would be more appropriate to state the assumptions that were made in the model. Suggest replacing the sentence with the following "According to the hydrologic model (BC, 2021), groundwater underflow in the uppermost 32.8 feet (10 meters) of the alluvial aquifer beneath the TSF Buttress and Embankment averages approximately 620 gpm (1,300,000 m ³ /year). The flux of groundwater in the assumed 10-meter zone of interaction beneath the facility was incorporated into the model by accounting for the volumes of groundwater that move through the groundwater system beneath the facility on an annual basis."	WTR	Revision not accepted. The summary statement is appropriate with the details available in the citation provided.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		173	"...concentrations of antimony, arsenic, copper, manganese, mercury, and thallium above the strictest potentially applied water quality standards." - As written, it sounds like these constituents are consistently above the standards, which is not the case. Please revise.	WTR	Revision not accepted. The summary statement is appropriate with the details provided in the referenced table.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		174	" <i>Upon placement of the geosynthetic cover, ...</i> " - In this passage it should be stated that the groundwater quality predicted below the TSF Buttress is improved compared to the current conditions. Removing the Hecla Heap and SODA is anticipated to improve groundwater significantly in this area. It would be good to clarify that groundwater arsenic and antimony concentrations are predicted to be orders of magnitude lower than the current conditions as a result of mining. This is not captured in what is written. Could be restated as follows. "Upon placement of the geosynthetic cover on the TSF Buttress, infiltration is significantly reduced and arsenic and antimony concentrations in groundwater decrease but remain elevated above groundwater standards due to the recharge of residual water within the TSF Embankment and Buttress. However, the predicted arsenic and antimony concentrations in groundwater during the post-closure period are significantly lower than the existing conditions due to the removal of legacy facilities (Hecla Heap and SODA) during mining. Based on average concentrations from MWH-A04, arsenic and antimony in groundwater are 1.8 and 0.06 mg/L respectively under existing conditions. Arsenic and antimony concentrations are predicted to be an order of magnitude lower for the post-closure period due to the removal of the legacy facilities but still elevated above background groundwater quality as defined by MWH-A01."	WTR	Revision not accepted. The current description appropriately describes the predicted groundwater chemistry.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		175	Maximum value for manganese is less than SW quality criteria and should not be shaded. Please revise.	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		176	Not all of the shading in this table is correct. The values need to be re-checked against the standards and shaded appropriately. Please revise.	WTR	Revisions made to the shading for Mn and Tl with text revised accordingly (SDEIS page 4-192, paragraph 2).
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		177	" <i>Post-mining the application of a low permeability geosynthetic cover to the TSF Buttress and Embankment means any toe/pop-out seepage would report to groundwater</i> " - This could be seized upon as representing a potential groundwater impact, particularly given the high concentrations of arsenic and antimony in toe/pop-out seepage. In reality the volumes of toe/popout seepage are very low. This could be clarified in a footnote.	WTR	Revision not accepted. The volume of pop-out and toe seepage are presented in Figure 4.9-3.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		178	" <i>This minor seepage would interact with groundwater in the uppermost 32.8 feet (10 meters) of the alluvial aquifer</i> " - Please clarify that this mixing zone thickness is a modeling assumption, not an established fact.	WTR	Revision made. "would interact" replaced with "is predicted to interact".

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Resources Idaho, Inc.)					
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		179	Table caption or supporting text should specify that values are for tailings solids and not pore-water chemistry.	WTR	Table 4.9-5 title revised to "Details of Tailings Solids Composite Samples".
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		180	" <i>Representative process water chemistry data were obtained from HCT tailings decant solution...</i> " - Incorrect as stated as decant water is not from an HCT but rather it is from pilot testing; remove 'HCT tailings' to correct this description.	WTR	Revision made. "HCT" removed from the description of tailings decant solution.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		181	" <i>When tailings are sufficiently consolidated to allow equipment to access the TSF surface around Mine Year 23,...</i> " - The cover placement starts around year 19 and finished in or by 23. Please clarify that covering instantaneously in year 23 is a conservative model assumption, not the actual cover emplacement plan.	WTR	Revision made. The sentence has been revised to read "When tailings are sufficiently consolidated to allow equipment to access the TSF to complete soil cover placement by around Mine Year 23,..."
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		182	" <i>Through this period (approximately 40 years), TSF surface water would be routed to the water treatment plant before discharge to Meadow Creek.</i> " - The period described is 25 years (Year 15-40), not 40 years. Also, this statement is incorrect. From years 23 to 40 the consolidation water is collected underneath the cover. The "surface" water is clean as there is a geosynthetic and up to several feet of soil/rock/growth media between the tailings and the ground surface. The surface water reports to Meadow Creek during this time period. The following revision of the paragraph is proposed: "When tailings are sufficiently consolidated and mine equipment can safely access the TSF surface, a geosynthetic cover would be placed over the tailings to reduce meteoric water contact with tailings material and infiltration into the TSF. Cover placement will begin around Year 19 and will be complete by Year 23. During and following cover placement, tailings would continue to consolidate and produce water. The collected consolidation water would be directed to the water treatment plant for 40 years into post-operations. Surface water from the TSF after cover placement reports directly to Meadow Creek during this time."	WTR	Revision made. "approximately 40 years" has been revised to "approximately Mine Year 40".
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		183	" <i>To summarize, these mine-affected waters include:... post-closure TSF facility solutions.</i> " - Please remove from this list. "Post closure TSF facility solutions" would not be used in ore processing, which will have long since ceased.	WTR	The statement has been clarified to indicate that the list includes waters subject to water treatment.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		184	" <i>The Site-Wide Water Balance model (Brown and Caldwell 2021a) ...</i> " - Global / all chapters - Perpetua was the author of the SWWB model for the 2021 MMP. Please correct for the FEIS.	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		185	" <i>A 120-year precipitation record was utilized to develop percentile estimates for meteoric inputs to the water balance (5th through 95th percentile ranges)...</i> " - While some precipitation percentiles are	WTR	The parenthetical "(5th through 95th percentile ranges)" has been removed to clarify the statement.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Resources Idaho, Inc.)			reported, the SWWB results generally look at percentiles of the OUTPUTS not those inputs. Please revise.		
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		186	"Any short-term volumes in excess of the water treatment capacity (i.e., following a large storm event) would result in water storage within the TSF and/or contact water ponds." - Please clarify this statement: any excess stormwater would not be directly transferred to the TSF, but will effectively remain there by foregoing reclaim and preferentially consuming other water in ore processing. The net effect is the same as to water balance.	WTR	Revision not accepted. There is no representation that excess water would be transferred to the TSF.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		187	"During warmer months, retention times for contact water in ponds would be up to 34 days resulting in warmer water treatment plant feeds with the potential to increase Meadow Creek temperatures downstream of the treatment plant outfall by up to 2.5oC." - Please clarify here that in this scenario, we would have the option of directly treating and discharging cooler dewatering water, and using the stored contact water in ore processing. Also confirm the value 2.5oC; this appears to be quite high vs. past modeling.	WTR	The text reflects the temperature information provided by the Water Management Plan.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		188	"Under an IPDES permit, the water treatment plant effluent would be directed to Meadow Creek at a location upstream of the Hangar Flats pit when flow augmentation is required and otherwise to the East Fork SFSR for the remainder of operations (i.e., when Hangar Flats groundwater pumping results in decreased Meadow Creek baseflow)." - bolded passage is misplaced; move to earlier in sentence after "required".	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		189	"The first-stage iron coprecipitation would be modified to include gypsum precipitation to reduce sulfate concentrations. The second-stage iron coprecipitation would then be converted to ettringite prearecipation which would reduce sulfate and TDS concentrations to the target levels for treatment plan effluent. Cyanide would be treated using a two-stage alkaline oxidation process that converts cyanide to carbon dioxide, nitrogen gas, and water. " - The description provided in here is based on an earlier draft version of the WMP, not the Final December 2021 version (The December 2021 version is referenced in the SDEIS and posted as a supporting document by USFS). Please replace it with the description from the December 2021 version (page 8- 33 of the WMP), "The treatment process begins with chemical oxidation followed by iron coprecipitation to remove a significant fraction of dissolved metals. Organic sulfide precipitation of mercury is provided. Softening will be performed via lime and soda ash to remove calcium and magnesium. Adjustment of pH will be provided in advance of ultrafiltration to remove carryover solids from the solids contact clarifier and prevent particulate fouling of the RO membranes. RO membrane treatment will separate the dissolved solids into a concentrated brine while the permeate water will be pH adjusted and re-mineralized prior to discharge to Meadow Creek via an IPDES-permitted outfall. The concentrated brine will be sent to an evaporative crystallizer that converts the dissolved solids into a crystalline solid, which will then be dewatered. Distillate from the evaporative crystallizer will be pH adjusted prior to discharge to Meadow Creek." Note that the treatment process described in the final version of the WMP will result in a higher water quality discharge to Meadow Creek compared to the draft version of the WMP.	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		190	"...and thereafter dewatered and disposed of in a location constructed in the TSF above the cover r." - Please correct: final cover of the TSF would be deferred in areas of residual solid disposition.	WTR	The Project description calls for water treatment residuals to be placed in a repository above the cover when the TSF closure is completed and then reclaimed following completion of water treatment activities.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		191	"At the start of closure, water treatment plant effluent would be discharged to the East Fork SFSR until the cover of the TSF is completed (approximately nine years to allow for tailings consolidation, cover installation, and stream channel restoration). Once the TSF cover is completed, the treatment plant and	WTR	Revision made. The revised text reads "The operations phase water treatment plan would treat mine-impacted water and discharge to the East Fork SFSR through reclamation of operational components through Mine Year 18. Prior to Mine Year 15, the reclamation and closure phase

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Perpetua Resources Idaho, Inc.)			<p><i>discharge would be relocated to Meadow Creek, nearer the TSF, for the duration of its operation (to approximately Mine Year 40). "</i></p> <p>The text presented here does not align with the plan described in the final version of the WMP (BC, Dec. 2021, see previous comment). There will actually be two separate water treatment plants (WTPs); the operations phase WTP will continue to treat mine-impacted water collected from the truck shop and plant site ponds until mine year 18. The reclamation and closure WTP will be constructed prior to mine year 15 and will be located on top of the TSF Buttress on private property where it will operate until approximately mine year 40 (reference section 8.7, 8.7.1, 8.8, and Table 8-17 of the WMP [BC, Dec. 2021]). Please revise text to clarify that there will be two separate treatment plants for operations and closure; the operations WTP will not treat process water and will not be relocated.</p>		water treatment plant would be constructed on top of the TSF buttress where it would treat mine-impacted water through the completion of water treatment requirements estimated to be in Mine Year 40."
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		192	<p><i>"These temporary systems would utilize trailer- mounted or skid-mounted equipment packages containing membrane treatment and/or iron coprecipitation systems that can be set up with limited lead time. Figure 4.9-10 illustrates the construction period water treatment flowsheet. "</i></p> <p>-As stated, the temporary systems would be equipment packages containing membrane treatment and/or iron coprecipitation systems, but the referenced Figure 4.9-10 is the treatment flow sheet for only the membrane alternative. Please revise the last sentence of the quote above to state, "Figure 4.9-10 and Figure 4.9-11 illustrate the construction period water treatment flowsheet." Please also update the captions for Figures 4.9-10 and 4.9-11 to state either could be potential flowsheets for the construction period.</p>	WTR	Revision made. Reference made to both Figures 4.9-10 and 4.9-11.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		193	This flow sheet is from a draft version of the WMP and does not reflect the information provided in the final version of the WMP, dated December 2021 (see previous comments), which included RO with an evaporative crystallizer. Please update the figure to match that shown in Figure 8-5 on page 8-34 of the Final version of the WMP.	WTR	Revision made. Figure updated.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		194	<i>"...and from the Yellow Pine and Hangar Flats pits in the Yellow Pine backfill."</i> - Statement is incorrect; Yellow Pine backfill is comprised primarily of material from West End. Please revise.	WTR	Revision made. West End pit added to the list of sources for Yellow Pine pit backfill.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		195	<i>"Midnight pit backfill would be mounded at closure to promote runoff and the highwall and backfill material would be unsaturated. "</i> - This is the correct statement; previous statement referring to inundated backfill at Midnight Pit is incorrect. Please revise.	WTR	Revision made per comment regarding Midnight pit material inundation.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		196	<i>"Representative leachate chemistry for the non-PAG and PAG pit wall rock, talus and backfill material were obtained from humidity cell data associated with the backfill material..."</i> - Bolded words should be corrected to "development rock and ore material" as the wall rock and talus represent a combination of both development rock and ore-grade material.	WTR	Revision not accepted. The test results were associated with the lithologies expected to be present in the backfill material.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		197	<i>"Further details of the modeling are available in Brown and Caldwell 2021e and SRK 2021a "</i> - The SRK Characterization report is incorrectly referenced here. See previous comment about SRK references to revise.	WTR	SRK references corrected.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Resources Idaho, Inc.)					
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		198	<p>"The tracking analyses indicated that these destinations were typically surface stream segments in Meadow Creek, the East Fork SFSR, or Sugar Creek." - Discussion here should include explanation of why receiving stream segments percentages shown on figure 4.9-20 do not sum to 100%.</p> <p>Suggest the following additional language. "In each sub-basin the majority of the particles report to a stream; however in every case there are some particles that remain in the groundwater at the end of the 100 year simulation. The degree of this effect varies between the stream basins because the geometry of each basin is different with respect to groundwater flow gradients and speed, which in turn causes some particles to move more slowly and necessarily take longer to reach a discharge point to surface water. "</p>	WTR	Revision not made. The additional description of the figure is not required.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		199	<p>"Approximately two percent of the groundwater particles originating from the Yellow Pine pit backfill are predicted to reach those groundwater areas which could observe an associated increase in groundwater antimony and arsenic concentrations. " - The application of the particle tracking results is not used correctly here. Even though 2% of the particles were estimated to originate from the backfill, this does not automatically relate to groundwater concentrations, nor does it speak to the potential for the pore water to degrade groundwater. The potential to degrade groundwater depends upon the existing groundwater chemistry and how different it is from the pore water leaving the backfilled pit. In the case where the existing groundwater is already impacted and concentrations are higher than the pore water, there could actually be an improvement in existing groundwater conditions. This potential to improve previously impacted groundwater downgradient of the YPP needs to be acknowledged.</p> <p>Furthermore, the conclusion that some areas would see major negative effects, is premised on the assumption that these areas are not already impacted by legacy mining materials and in-situ mineralized rock. The cited wells (i.e., MWH-A17 and SRK-GM-04S) are only drilled to about 100' and are screened at elevations of 6100' and 6040' respectively; approximately the same elevation as the existing pit lake (6040') and elevation of future backfill. These screen elevations may not be sufficiently deep to adequately assess existing water quality of the receiving alluvial or bedrock aquifer where it could be impacted by pit backfill materials or pit wall contact. It is expected that water quality in the bedrock aquifer and alluvial aquifer downgradient of the YPP ore body and at depths below shallow wells, is already impacted by spatially extensive mineralization and alteration in the area as well as legacy facilities. Please revise the statements where the results of particle tracking analysis are used.</p>	WTR	The SDEIS statement indicates the potential for arsenic and antimony to transport from the pit area to receiving groundwater. As stated, this transport could raise groundwater antimony and arsenic concentrations compared to their current conditions.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		200	<p>"The effects of the infiltration of leachate from the TSF, TSF Buttress, stockpiles and Midnight pit backfill, groundwater interaction with the Yellow Pine and Hangar Flats pit backfills, and West End pit lake on groundwater chemistry would be minor to major depending on the existing condition of receiving groundwater, permanent, and localized. " - Facilities that receive caps, particularly the buttress, would have temporary/short-term impacts not permanent. The remaining permanent impact if any, would be minor. Please clarify/correct.</p>	WTR	The aggregate effect of mine facilities on groundwater chemistry would be permanent.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		201	<p>"The Forest Service would require that where haul roads pass within 25 feet (slope distance) of surface water, dust abatement would only be applied to a 10-foot swath down the centerline of the road." - Please strike this sentence. This is infeasible and ineffective for haul roads which are roughly 100' wide and is likely a carryover from the exploration Golden Meadows EA which applied to roads that are only 12 to 30' wide or so.</p>	WTR	This statement has been revised to read "... dust abatement would only be applied in the center portion of the roadway".
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		202	Please clarify what the values in the tables represent (averages, mins/max) and what the red coloring indicates.	WTR	Explanations of the data on the table have been added to the legend.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		203	"Immediately downstream of the Yellow Pine pit on the East Fork SFSSR at node YP- SR-4 (above the confluence with Sugar Creek), predicted surface water chemistry is similar to existing conditions with some variability in predicted antimony, arsenic, and mercury concentrations during the operating and initial closure period " - There is a significant reduction in arsenic and antimony concentrations during the operation and post closure period at YP-SR-4 with respect to existing conditions. The text as written indicates that the predicted concentrations for this time period are similar to existing conditions, which is not correct. Please quantify these values rather than use subjective descriptors: A 40% reduction in closure, and more than that in operations, is not adequately described by "similar" or "with some variability" to existing conditions; it is unquestionably lower with respect to the key COCs arsenic and antimony; please describe as such.	WTR	The variability in the concentrations during the operating period, namely the maximum concentrations predicted early in the operating period, preclude a conclusion that the concentrations are reduced for the entirety of that period.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		204	"During operations, mercury concentrations are greater than the most stringent applicable water quality standard because the surface water in upper West End Creek is above the standard under existing conditions" - Clarify that this water is routed around legacy features where presently that mercury gets dropped out, and in operations will just flow past.	WTR	Revision not made. The explanation for the higher mercury concentrations is appropriate.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		205	"Similarly, predicted arsenic concentrations decrease relative to existing conditions during the operating period then recover to a concentration comparable to existing conditions in the post-closure period. " - Table 4.9-21 shows reductions in As and Sb concentrations on the order of 30-40% relative to existing conditions. Effects should be described as moderate (beneficial) impacts, not as comparable concentrations.	WTR	The variability in the concentrations during the operating period, namely the maximum concentrations predicted early in the operating period, preclude a conclusion that the concentrations are reduced for the entirety of that period.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		206	"This suggests that a naturally-occurring mechanism reduces mercury concentrations in the creek between the sample locations upstream and downstream of the pit area. " - This could be clarified - mercury is reduced as the stream flows through the upper West End waste rock dump and it deposits in the pore space of the dump. While the physics of the porous media flow and the resulting retention of particulate mercury is "naturally occurring" the dump is not.	WTR	Revision made. The term "naturally-occurring mechanism" has been replaced by "mechanisms that retain particulate mercury".
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		207	"Diversion of West End Creek around the pit area during operations has the potential to affect the naturally-occurring reduction in mercury concentrations, allowing higher upstream concentrations to appear in the downstream segment" - The reference to "naturally occurring mercury reduction" should be removed. Suggested rewording of the paragraph is, "Diversion of West End Creek around the pit area during operations has the potential to affect the mercury concentrations by eliminating a current source of attenuation that occurs as water moves through the legacy development rock facilities in the area. Therefore, the SWWC model assumes that the higher upstream mercury concentrations would occur in the downstream segment when the West End Creek diversion is constructed. Despite this conservative model assumption, mercury concentrations are predicted to remain below the surface water standards."	WTR	Revision made per comment regarding reduction in mercury concentrations.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		208	"Effects of the project on surface water concentrations (in Sugar Creek) are expected to be negligible relative to applicable standards and calculated human health criteria, permanent, and localized. " - It should be acknowledged that there is a moderate positive effect on surface water concentrations relative to existing conditions as a result of mining. Please revise.	WTR	The variability in the concentrations during the operating period, namely the maximum concentrations predicted early in the operating period, preclude a conclusion that the concentrations are reduced for the entirety of that period.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		209	"Air emissions from the project have the potential to contribute metals to the ground surface via wet and dry deposition that have the potential to affect surface water chemistry. Most of these contributions would be in the form of particulate matter, but a portion of the local aerial deposition of mercury may also occur in elemental form. Total mercury emissions from the project are predicted to be approximately 13.6 pounds of mercury per year." - This description is inaccurate and misleading to the	WTR	The text has been revised to include a discussion of the deposition modeling per the Air Quality analysis (i.e., 0.056 g/km2/year versus the REMSAD model results for baseline deposition).

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Resources Idaho, Inc.)			reader. The presented emissions would not be aerially deposited, as the heading suggests. The modeled deposition rate of Hg due to the project is well under 1 g/km ² per year, a value that is far less than 1% of background mercury deposition as quantified in the REMSAD model.		
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		210	These paragraphs should reflect and discuss the air quality analysis report, which quantifies Hg emissions and also models Hg deposition based on project emissions and relative to background deposition rates. These values are in the SDEIS document and the reader to should be directed to them. Background deposition rates for Hg from the REMSAD model in the project vicinity are 12.7 to 13.9 g/km ² per year; modeled deposition from project emissions is, at most, 0.056 g/km ² per year...far less than 1% of background. This can not be equated to a "minor to moderate" effect on particulate mercury loads in streams due to project activities due to aerial deposition. It is less than negligible. Please revise to include project- specific information and analysis.	WTR	The text has been revised to include discussion of the deposition modeling per the Air Quality analysis (i.e., 0.056 g/km ² /year versus the REMSAD model results for baseline deposition).
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		211	"Predictive modeling indicates that mine facilities and water treatment would contribute dissolved..." - Please rewrite to clarify. Water treatment would not degrade water quality, based on IPDES antidegradation regulations.	WTR	"... and water treatment" has been removed from the text.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		212	"An incremental increase in organic carbon content due to wastewater effluent (as described above) would yield an incremental increase..." - please replace 'would' with 'could'.	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		213	"For Meadow Creek, the East Fork SFSR, and Sugar Creek, predicted total mercury concentrations varied up to 5 ng/L compared to existing conditions which ranged between 2.5 ng/L and 159 ng/L." - Please clarify whether "existing conditions" refers to SGP baseline data, model predictions, or Holloway et al data.	WTR	A citation to Holloway has been added for the existing conditions values.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		214	"Ifupstream total mercury concentrations in West End Creek persist to downstream areas of the creek due to its diversion around the West End pit area, application of the methylation ratio would indicate a potential increase of methylmercury concentrations up to 0.9 ng/L in that portion of West End Creek. " - The use of a ratio developed for Sugar Creek cannot necessarily be applied to West End Creek as the two streams have differing morphology with West End Creek being steeper gradient and more incised, reducing wetland area and associated methylation potential. West End Creek is about 25% gradient. Sugar Creek, Meadow Creek, and EFSFSR range from <1 to 7%, and usually <5%. From surface water monitoring data collected as part of the Surface Water Quality Baseline Study (HDR, 2017) and collated by Brown and Caldwell, mercury concentrations show a positive correlation to the proportion of Total Suspended Solids (TSS). The positive correlation between total mercury and TSS indicates the majority of mercury is present in particulates coarser than 0.45 µm and therefore less likely to methylate or be bioavailable. These results suggest mercury methylation is unlikely to be significant in the Stibnite district owing to the majority of mercury being associated with the particulate or 'total' fraction. Based on the site data collected as part of the Surface Water Quality Baseline Study (HDR, 2017) and collated by Brown and Caldwell, the mercury budget available to methylate is small, being less than 1% in any sample and less than 0.1% in most samples. Therefore, the 2% methylation ratio is highly conservative based on the available data. Please revise the ratio or acknowledge that it is very conservative.	WTR	An acknowledgment to the conservatism of the estimate has been added to the text.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		215	Paragraph 2 - P 260 discusses sediment generation and management practices; It seems applicable here to also include discussion on interim measures to reduce sediment production in the East Fork of	WTR	The statement "However, measures that reduce sediment production in the East Fork of Meadow Creek are an early component of the Project. These measures would mitigate the

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Resources Idaho, Inc.)			Meadow Creek early in the project through the Blowout Creek Restoration, and ultimate reclamation of that drainage. This is a significant facet of the project that improves water quality. Please revise.		largest sediment source present under existing conditions." has been added following the first sentence of the Sediment section.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		216	"Perpetua would limit the potential for sedimentation impacts by following conditions in the Dewatering Practices section of their current Multi-Sector General Permit, or the Multi-Sector General Permit..." - Substantial portions of the mine site and several off-site facilities are expected to have IPDES coverage under the MSGP during construction and operations, as was discussed in the Water Management Plan. This coverage, which may include haul roads, access roads, maintenance and logistics facilities, and other parts of the SGP not included in the industrial Individual IPDES permit, is outlined in the SGP Water Management Plan (BC 2022) and will be administered by IDEQ. For the FEIS, additional information about MSGP coverage should be added for clarity.	WTR	This section is focused on Yellow Pine pit lake dewatering. Controls for other facilities under the Multi-Sector General Permit have been added to the previous paragraph.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		217	This figures indicates that high pH equates to lower methylation. Whereas the project site has elevated pH, please address/discuss the implication of this in the text.	WTR	Predicted pH conditions associated with the site change very little compared to existing conditions.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		218	"To protect surface water, snow removal standards or performance would include depositing snow and ice away from stream channels; maintaining appropriate snow floor depth to protect the roadway;" - Please remove this sentence. This is a remnant from the exploration EA. It is not a requirement and it is a safety hazard; the road would be plowed to the surface as per the first part of this paragraph.	WTR	The requirement has been applied as described in Chapter 2.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		219	"Mining and vegetation removal..." - Please add '...and subsequent restoration plantings.' as they are also considered in modeling.	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		220	"Permitted discharge of treated water or non-contact water to surface water." - please delete 'permitted'; non-contact water is not "permitted" in the sense of needing a discharge permit, and the word is not important to the meaning of the sentence.	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		221	Section 5.1 of the Fisheries Specialist Report indicates that this 6.6C increase applies across the analysis area of the EFSFSR upstream of Sugar Creek. This is misleading. Most of the temperature increases are less than 1C and through much of the EFSFSR they actually go down (noted by "-" in this table). Please revise discussion.	WTR	The table of predicted temperature increases shows the location of the maximum increase to be Meadow Creek above the EFMC confluence and that other stream reaches are affected to a lesser extent.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		222	"...residence time of surface flow in the low-gradient sinuous restored stream channel would allow warming of temperatures above existing conditions ..." - Lack of shade is also an important factor; suggest adding to discussion.	WTR	Revision made to acknowledge lack of shade.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		223	"...and industrial supply wells lowers water levels and groundwater discharge to surface water during operations." - Please clarify it is not throughout operation. The HF pit is only below valley bottom for about 18 months, then it is backfilled and groundwater recovered by year 8. Please revise.	WTR	Revision made to acknowledge groundwater recovery during the operational period.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		224	"In addition, underdrain flow from the TSF is intercepted during operations ". - This statement is incorrect; TSF underdrain water is assumed to be discharged to Meadow Creek for the base case of the water modeling. In the base case, it was assumed that it would meet IPDES permit limits to be directly discharged into Meadow Creek without treatment. It would be use in processing or treated before discharge if it turns out to be impacted by the TSF - but again that is not the base assumption. Please revise.	WTR	Revision made. The sentence regarding underdrain flow has been removed.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		225	"On the Meadow Creek segment atop the reclaimed TSF, temperature reductions would occur more slowly remaining warmer than existing conditions after 100 years. " - This is not accurate. As shown in Table 4.9-24, we get back to existing conditions somewhere between 50 and 100 years. Please revise.	WTR	SDEIS Figure 4.9-28 shows that the predicted EOY112 temperatures remain above the existing conditions for the TSF area.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		226	"In the Yellow Pine pit area and downstream, ..." - To clarify this statement, please add to beginning: 'During operations, in the YPP area...'	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		227	"Achievement of these predicted temperatures would depend on the effective and durable installation of the Stibnite Lake feature." - This is an unnecessary statement that could be speculated about any constructed feature. With respect to sedimentation, an ancillary benefit of the Blowout Creek repair is that Stibnite Lake will remain a lake far longer than the present YPP lake would under No Action (and note Rio ASE calculated fill time / issued to USFS previously). Please remove.	WTR	Revision not accepted. The statement regarding effectiveness and durability is responsive to input from other comments regarding the expected long-term performance of the Stibnite Lake feature and acts to introduce the Blowout Creek repair topic.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		228	P. 274, paragraph 4 includes discussion of sediment control measures and restoration effects for Blowout Creek that should also be included in (or moved to) the sedimentation discussion in "Sediment". Here, the allusion is that its primary purpose is to improve the durability of Stibnite Lake, which is not the case. It's primary purpose is to reduce sedimentation and improve water quality in the EFSFSR. Please revise.	WTR	A description of the effects of Blowout Creek repair has been added to the Sediment sub-section of the Final EIS.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		229	P. 4-275 paragraph 3 is inconsistent with the preceding paragraphs. If it is intended to be a summary, it should not simply focus on the temperature increases because singular number are difficult to interpret out of context. Please validate the cited values or simply refer the reader to the tables. 3C in EFSFSR "below YPP area" is misleading; the author should clarify that once Sugar Creek enters the system, the simulated maximum increase is 1C. 10C in Meadow Creek is relative to the piped condition; the paragraph introduction states "compared to existing conditions"; the increase above baseline in Meadow Creek is 6.6C. Please evaluate and revise.	WTR	The text has been revised to indicate the effects of Sugar Creek on temperatures downstream of the Yellow Pine pit area. Increased average temperatures in the TSF area compared to existing conditions are approximately 6.6°C but there are segments where the temperature increase is up to 10°C. This has been clarified in the revised text.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		230	"Compared to existing conditions, project operations are predicted to increase temperatures in West End Creek by up to 9oC and the East Fork SFSR below the Yellow Pine pit area by up to 3oC. Upon closure activities, Meadow Creek temperatures are predicted to increase by up to 10oC as the stream channel is restored atop the TSF while formation of the West End pit lake raises temperatures in West End Creek by approximately 4oC. With the exception of the West End Creek segment below the pit area, predicted temperatures return to existing conditions over a period of approximately 100 years as stream	WTR	SDEIS Figure 4.9-28 shows that the predicted EOY112 temperatures remain above the existing conditions for the TSF area.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p><i>restoration and riparian plantings along with the moderating effect of the Stibnite Lake feature take effect (see also Section 4.9.3) "</i></p> <p>- The author should clarify that the West End Pit Lake is not predicted to have a surface outflow, and the simulated increase in West End Creek does not significantly impact temperatures in Sugar Creek because the flows in West End are very low.</p> <p>-The last sentence is incorrect: it does not take 100 years for temperatures to return to existing conditions everywhere else on site. The only location of significant lasting temperature increase is on the TSF, and even there, temperatures return to baseline sometime between 50 and 100 years. Most of the EFSFSR temperatures actually decrease relative to existing conditions as shown in Table 4.9-24 visualized with the dashes in the maximum temperature increase for the project column. Table 4.9-24 list 36 rows of area-season-metric combinations. 18 rows either have a dash or have temperature increases that are less than or equal to 0.2C of baseline. 24 rows have a dash or temperatures increases less than or equal to 0.5C from baseline.</p>		
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		231	" <i>The potential for surface water quality impacts from accidental fuel or chemical spills along the mine access roads would be comparable between the alternatives</i> ". - Please correct this unsupported statement. JC has nearly 4X the road length within 100' of streams. Thus, the potential for SW quality impacts from fuel or chemical spills cannot reasonably be described as comparable; the BL Route has demonstrably lower risk.	WTR	This sentence has been removed from the EIS.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		232	" <i>The technical adequacy review identified the following sources of model uncertainty and potentially non-conservative model assumptions:</i> " - If non- conservative model assumptions are being listed, the conservative ones, of which there are many, should also be so listed to give the reader a full picture of how modeling was conducted. It is also notable that "non-conservative" with respect to one thing (say, water supply from contact water runoff) is "conservative" with respect to something else (leachate volume reporting to GW).	WTR	Non-conservative assumptions are disclosed per NEPA requirements.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		233	" <i>...actual long-term conditions for the proposed mine facilities could vary the rate of sulfide oxidation along with the leachate pH and/or leached analyte concentrations.</i> " - Please note for the reader here that actual long-term conditions (i.e. site data) show that acid generation has not occurred from historical mine waste despite exposure at surface for several decades. Circum- neutral to moderately alkaline baseline surface water and groundwater chemistry (and pit lake chemistry) also supports the assumption there has been no/limited acid generation from historical mine wastes.	WTR	The actual site conditions associated with acidic drainage are noted previously in SDEIS Section 4.9.2.2.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		234	" <i>First-flush releases from the development rock material could cause short-term increases in downstream concentrations above and beyond what is currently predicted by the model</i> ". - Please note here (or correct this statement to note) that it is very likely the first flush chemistry will occur during operations and will be managed as contact water, therefore this will have minimal effect on in-stream concentrations.	WTR	The circumstances regarding first flush chemistry are described in SDEIS Section 3.9.4.2.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		235	" <i>Air temperature correction factors used to scale laboratory reaction rates to field conditions by the model could underestimate actual reaction rates and chemical releases from mined materials, and hence, surface water quality impacts.</i> " - The term 'correction factors' is misleading here. It should be clarified that <i>measured</i> (not arbitrary) air temperature data are used to scale laboratory data to field conditions.	WTR	"Correction factors" has been revised to "scaling factor".
Alan Haslam (Vice President, Permitting, Perpetua		236	" <i>The surface water quality model predictions do not include mass loading inputs from permitted IPDES outfalls that would be required for the SGP.</i> " The statement that the surface water quality model predictions do not include mass loading inputs from permitted IPDES outfalls is incorrect. Treated effluent from the water treatment plant has been incorporated into the models and this bullet can be	WTR	The EIS analysis uses the predicted analyte concentrations associated with water treatment but does not include any mass loading requirements from the IPDES permits.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Resources Idaho, Inc.)			removed from this section. Reference to a water treatment sensitivity scenario should also be removed from this section.		
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		237	"Additionally, mercury inputs from atmospheric deposition caused by the SGP have not been considered in the model." - As noted in the air quality section of this SDEIS, atmospheric deposition of Hg caused by project emissions represents a fraction of 1% of the background Hg deposition noted in the REMSAD model. This should not be cited as an uncertainty in the SW quality model when there are data available within this report that clearly indicate that this would have a negligible impact on SW quality.	WTR	The text has been revised to include discussion of the deposition modeling per the Air Quality analysis (i.e., 0.056 g/km ² /year versus the REMSAD model results for baseline deposition).
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		238	"Model-predicted concentrations generated by the SWWC Model are for the dissolved fraction only and may underpredict concentration levels for constituents such as mercury that have been shown to occur in particulate form". The particulate form of the constituents that will be in surface water runoff will be managed during operations. A geosynthetic cover would be placed on the facilities at closure and overlain by an inert soil/rock layer and growth media and revegetated. These controls will limit the potential for particulates to contribute to constituent load in the surface water system. Please revise.	WTR	Controls on particulate matter in surface water could be substantially effective, but any particulate matter entering the stream could affect total fraction analyte concentrations.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		239	"The lined Stibnite Lake feature would receive inflow from the cover material in contrast to the existing groundwater inflow" - Add the word 'minimal' here before 'existing' as statement refers to inflow from bedrock.	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		240	"The current temperature model does not incorporate any potential cooling effects from subsurface inflow into the Stibnite Lake feature," - This should be identified as a conservative modeling assumption. Any groundwater influence is going to be beneficial not detrimental to temperature.	WTR	The text has been revised to indicate that this is a conservative assumption.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		241	"Qualitatively however, insufficiently effective closure activities and/or adverse changes in broader climate conditions could result in higher than predicted stream temperatures" - Please note that in this case, the mitigation measures described in Section 4.9.3 would apply, and that "higher than predicted" stream temperatures would prevail in unaffected streams not just the SGP restoration projects. Please revise.	WTR	The mitigation measure in the SDEIS Section 4.9.3 speaks directly to this uncertainty in future temperature conditions.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		242	"At less than full design efficiency" - This sentence is likely unclear to the reader. Suggest this intro clause should be replaced with "Even when shade is assumed to be only 40 percent of that designed..."	WTR	Edit has been made.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		243	"Without this temperature reduction, stream temperatures downstream of the Yellow Pine pit area could also be greater than existing conditions". - This is a misleading statement especially in light of the 40% shade sensitivity analysis shown later in this Chapter. Also, in EOY27 when temperatures on the TSF are simulated to be the warmest, the temperatures downstream of YPP are within 0.4C. The context of the increase should be included in these types of statements through out this Chapter and the Fisheries Report. Please revise.	WTR	Revision not accepted. The statement appropriately describes the predicted water temperatures downstream of the Yellow Pine pit area.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		244	"Under the No Action Alternative, there would be no open pit mining or removal of legacy waste material at the mine site." - This disregards ASAOC activities. Please correct.	WTR	The text has been revised to acknowledge the ASAOC.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		245	"However, surface water quality changes caused by the 2021 MMP would effectively be irretrievable..." - This is a misleading statement; most of the changes are positive, and towards restoring beneficial uses, particularly in Meadow Creek. Please revise.	WTR	This text pertains not just to predicted geochemical effects on surface water chemistry but also to the effects of incidents and spills. These effects would be irretrievable until abated as described in SDEIS Section 4.9.4.2.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		246	"Under the No Action Alternative, there would be no open pit mining or removal of legacy waste material at the mine site." - This disregards ASAOC activities. Please correct.	WTR	The text has been revised to acknowledge the ASAOC.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		247	"Under the Johnson Creek Route Alternative, long-term losses of groundwater and surface water productivity would be the same as the 2021 MMP except that transportation-related impacts to surface waters in the Johnson Creek drainage could be greater in nature and/or extent." - This is correct; please note that it contradicts a faulty assumption made in Section 4.9.2.3 (see comment above). Please revise the earlier section.	WTR	No further response required. General in nature or position statement.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		248	There appear to be calculation errors in this table, e.g. Yellow Pine percentages sum to 85%. Please validate.	WTR	The table has been revised per the contents of Table 3-2 from the Comprehensive Baseline Geochemical Characterization Report (SRK 2021a).
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		249	"Greater variability is evident between the dissolved and total mercury sample averages. The variability in mercury results may be attributable to the generally low concentration values, differing amounts of particulate matter in the total mercury samples, laboratory protocol differences between the two studies, or different runoff conditions..." - It is likely worth noting that the USGS specifically samples at highest flow events, so their Hg numbers are elevated relative to PRII, which normally samples in mid-May. Please include that in discussion.	WTR	The table is intended to summarize the available USGS and Perpetua surface water data. The % difference columns have been removed from the table and a footnote added to reflect sample collection times.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)		250	"...much of the sediment entering the East Fork SFSR was derived from Sugar Creek, Meadow Creek, and East Fork Meadow Creek (i.e., Blowout Creek)". - Reclamation of EF MC is not discussed in sediment effects analysis, but is noted here as a significant source. Suggest clarifying this for the reader in the effects analysis.	WTR	A description of the effects of Blowout Creek repair has been added to the Sediment sub-section of the report.

Elizabeth Barnes	6652	4	p. 2-144 Why are no alternatives provided to the destruction of 23 mature cone-bearing whitebark pine? Can they not be worked around? What is the anticipated effect of noise pollution and land clearing on Clark's nutcracker, and what are implications for the impending listing of whitebark pine?	VEG	Mitigation measures to address the potential loss of whitebark pine have been added to the Final EIS in Section 4.10.3. Potential impacts to wildlife, including habitat removal and human presence and noise, are discussed in Section 4.13.2 Impacts to the whitebark pine are discussed in Section 4.10.2.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	91	“ <i>The 2021 MMP would impact 3,991.0 acres of modeled potential habitat for sensitive and forest watch plant species.</i> ” Please check and clarify how these numbers of acres are larger or nearly so than the total acres of vegetation cleared in the rows below. You cannot provide a total number of acres of modeled potential habitat since it would double count areas that are considered potential habitat for multiple species.	VEG	Text has been revised per the comment. Total acreage deleted. A range of acreages for the various sensitive and forest watch plant species has been added to the text based on Table 4.10-4. The same changes have been made under the Johnson Creek Route Alternative as well.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	92	“ <i>The 2021 MMP-related vegetation clearing would impact 3,563.7 acres, including primarily undisturbed areas for the Burntlog Route where an increase in the potential for non- native plant establishment and spread would be more deleterious.</i> ” These numbers are larger than the total acres of disturbance in Chapter 2 (Tables 2.4-1 and 2.5- 2). Check these numbers and update accordingly or clarify how and why these numbers are bigger.	VEG	No text revisions made. As described in the Vegetation Specialist Report and Table 4.10-5, this total acreage includes the maximum possible extent of tall tree clearing related to the power line as well.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	649	“ <i>Exploration activities for potential future mining development in the vegetation analysis area have likely impacted vegetation via removal and soil compaction at drill pad sites and temporary roads and will likely continue to do so as these activities continue.</i> ” Compaction is reversed upon reclamation by a variety of techniques. Please revise.	VEG	Text has been revised per the comment.” until reclamation occurs” has been added to the statement.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	650	“ <i>These RFFAs would result in loss of habitat, but all projects (private or federal actions) would have to meet the requirements of Section 7 of the ESA, which include consultation with federal agencies on listed plant species, completion of appropriate analysis documents, and compliance with agency-mandated reasonable and prudent measures to protect listed species.</i> ” ESA does not deal with general vegetation resources. This should be moved to 5.13 Wildlife and Wildlife Habitat including Threatened, Endangered, Proposed, and Sensitive Species.	VEG	No text revisions made. This statement pertains specifically to the whitebark pine, which is discussed in Sections 3.10, 4.10, and 5.10.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	651	“ <i>This project is located primarily along the East Fork SFSR and Meadow Creek at the mine site and would result in disturbance to vegetation</i> ” - Please provide a more accurate description here of vegetation impacts; these actions will also facilitate wetland restoration and reforestation where there were previously barren or poorly revegetated waste piles.	VEG	Text has been added per the comment.” Riparian and upland herbaceous vegetation” has been added to the end of the paragraph in row 1 of Table 5.10-2.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	652	Stallion Gold – Horse Heaven Project' - Please provide the rationale for including this project as an RFFA or remove. It does not meet the definition of RFFA per 36 CFR 220.3.	VEG	No text revisions made. This project is an RFFA due to the amount of surface disturbance associated with the project and potential for disturbance to vegetation.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	653	“ <i>Therefore, implementation of the No Action Alternative would present a minimal cumulative contribution to impacts to vegetation resources.</i> ” ASAOC is a part of the No Action Alternative. Please include. And as noted in comment above, ASAOC activities facilitate wetland restoration and reforestation where there were previously barren or poorly revegetated waste piles.	VEG	Text has been added per the comment.” Additionally, Perpetua would continue to comply with the reclamation and monitoring commitments included in the Stibnite Mine Site ASAOC Project, which focuses on restoring portions of Meadow Creek and the East Fork SFSR after removing mill tailings and mine waste.” has been added.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	654	<p>“ <i>The 2021 MMP would result in the largest contribution to mining- related cumulative impacts to vegetation communities with the Johnson Creek Route Alternative impacting approximately 251 acres less.</i> ”</p> <p>Please replace” the largest” with” a larger”</p> <p>Please define the impacts to the vegetation as these are not expressly stated.</p>	VEG	Text has been revised per the comment.” Largest” has been revised to” larger” .
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	655	<p>“ <i>Other past and present actions (Table 5.10-1) and RFFAs (Table 5.10- 2) have and would likely impact vegetation communities, occurrences of special status plants including whitebark pine, habitats for special status plants, and distribution of non-native plants throughout the analysis area.</i> ” Please provide the necessary information to show or indicate that these impacts would overlap spatially, particularly the RFFAs.</p>	VEG	No text revisions have been made. Due to the relatively large geographic range of the whitebark pine and other special status plant species in this area of Idaho, it is reasonable to assume that nearby past, present, and RFFAs have or would result in cumulative impacts in combination with the Project.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	656	<p>“ <i>For whitebark pine, the potential for cumulative impacts would be lowest under the Johnson Creek Route Alternative and highest under the 2021 MMP based on disturbance acreage and estimated number of trees removed.</i> ” Please move this statement to Section 5.13 Wildlife and Wildlife Habitat including Threatened, Endangered, Proposed, and Sensitive Species</p>	VEG	No text revisions made. Whitebark pine, even after its listing as a federally threatened species, is included in the Vegetation sections of the EIS.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	253	<p>“ <i>Approximately 347 acres (2 percent) of the analysis area occur in the Salmon-Challis National Forest (administered by the PNF); however, PVG data were not available for this area.</i> ” PVG data is available. Please incorporate PVG data from USFS in WBP modeled habitat.</p>	VEG	No text revisions made. PVG data was not provided by the Forest Service for portions of the Project located on the Salmon-Challis National Forest.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	254	<p>Please round the percentages to one decimal value as the summarized modeled habitat is not field verified and providing more decimal places of precision could be misleading.</p>	VEG	Text has been revised to only include percentages to one decimal value.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	255	<p>“ <i>Source: AECOM 2020e</i>” The table footnote references the AECOM 2020e model, however earlier text indicates this model was updated by Stantec 2022. Please update the reference or clarify why the table references the previous report.</p>	VEG	Text has been revised per the comment. The Stantec (2022) modeling effort citation has replaced the” AECOM 2020e” reference, where appropriate.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	256	<p>Please clarify how many total occurrences and subpopulations of Bent-flowered Milkvetch overlap the SGP analysis area and disturbance footprint</p>	VEG	Text has been added per the comment.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	257	<p>“ <i>Five subpopulations of a single occurrence (the Cinnabar Peak occurrence) of this species were documented during surveys in 2012, 2013 (HDR 2017g), and 2016 (Mancuso 2016, IFWIS 2017).</i> ” Please update data referenced from IFWIS 2017 to more recent data sources. These data are available from the USFS. The USFS is a partner with IFWIS and receives these data two times a year (January and July).</p>	VEG	No text revisions made. The Forest Service has indicated that a cutoff date for data for this EIS is 2017.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	258	“ <i>The other subpopulations of this occurrence and the other occurrences of this species are located outside the analysis area for the SGP.</i> ” Please clarify how many” other” subpopulations.	VEG	Text has been added per the comment.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	259	“ <i>Issue: The SGP would impact forested PVGs within Forest Service- administered land and could impact the ability of these areas to reach desired conditions.</i> ” Table 1.10-1 lists all these issues as” may impact” instead of” would impact” . Please use consistent language as” may” and” would” mean different things.	VEG	No text revisions made.” Would” is appropriate here as this is the term used throughout the analysis portion of the EIS.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	260	For the FEIS, please change any reference to WBP as a” candidate” or” proposed threatened” species to” threatened” species to reflect the changes in status the WBP has gone through over the course of the Perpetua NEPA process.	VEG	Text has been revised per the comment.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	261	“ • <i>Number of acres of whitebark pine occupied habitat impacted by the SGP.</i> ” Please clarify if this indicator and calculation is within the SGP disturbance area or the 300-foot buffered analysis area.	VEG	No text revisions made. It is explained further in Section 4.10.2 that potential impacts to the whitebark pine is based on direct effects (SGP footprint and overlap of occupied habitat acreage). Indirect effects (300-foot buffered analysis area) are included in the analysis but no acreages are associated with indirect effects.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	262	“ • <i>Estimated number of mature whitebark pine trees to be cut during SGP construction.</i> ” Please provide methods, reference, and context for how these estimated WBP numbers were calculated. The methods were designed by the USFS and not discrete counts; providing numbers is misleading and needs explanation. Please also clarify mature WBP trees vs cone producing trees from the survey methodology. This should be qualified as an estimate of cone producing trees observed during 2019 field season, which is not the same as an estimate of the number of mature trees cut during construction. Please add context to this indicator such that the number of whitebark pine impacted can be evaluated as a percentage of a greater whole.	VEG	Text has been revised per the comment to update the status of the whitebark pine per the listing on December 15, 2022. Additionally, the analysis and required protection measures as well as mitigation measures required by the Forest Service have been added to the Final EIS, specifically in Sections 3.10, 4.10, and 5.10, as appropriate.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	263	“ • <i>Presence of known occurrences of sensitive or forest watch plant species or occupied habitat within 300 feet of the SGP disturbance area.</i> ” Please provide acres of occupied habitat within the SGP disturbance, similar to the other indicators.	VEG	Text has been added per the comment.” and/or acreage of occupied habitat.....” has been added.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	264	“ <i>4.10.2 Direct and Indirect Effects</i> “ For this entire section, please provide support for the summary effects calls and clarify how the intensity, duration, and context were derived. It is unclear how the numbers of individual plants were calculated. Please clarify and provide a methods summary, reference, and context of how these numbers were calculated. Please include a percentage of the greater whole for context.	VEG	Text has been revised per the comment.
Alan Haslam (Vice President, Permitting, Perpetua	19325	265	Please clarify how these numbers were calculated and what datasets were used.	VEG	Text has been revised per the comment.

Resources Idaho, Inc.)					
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	266	<p>“Based on the results of the species-specific field surveys conducted for the SGP in 2019 (Tetra Tech 2020b), the 2021 MMP would impact approximately 259.4 acres of occupied whitebark pine habitat and would remove an estimated 1,236 individual trees, 23 of which would be mature, cone-bearing individuals. This would result primarily in localized, long-term and permanent, moderate impacts to the whitebark pine. Detailed calculations of impacts to whitebark pine occupied habitat and individual trees are reported in the SGP Vegetation Specialist Report Appendix F (Forest Service 2022g).” When reading this statement, it is unclear how these numbers were calculated. While this statement points to the SGP Vegetation Specialist Report Appendix F (Forest Service 2022g), that report does not provide clear methods for how these numbers were derived.</p> <p>Please clarify and provide a methods summary, reference, and context of how these estimated WBP numbers were calculated. These discrete reported numbers were derived from very broad estimates and categories from field surveys and not an actual count of individuals.</p>	VEG	Appendix F of the Vegetation Specialist Report contains details of the calculations in the footnotes for Table F-1 and Table F-2. Additionally, text has been added per the comment regarding the” estimate” of whitebark pine resources during the field survey in 2019 conducted by TetraTech.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	267	<p>“Construction of the 2021 MMP would impact several known occurrences of sensitive and forest watch plant species as described in the following subsections.” Please clarify under each species if there is any known occupied habitat/occurrences that are within the SGP footprint. Consider use of the number of acres of occupied habitat within the SGP disturbance as the indicator.</p>	VEG	No text revisions made. Descriptions of potential impacts to specific sensitive species, including known populations and modeled habitat, is presented in Section 4.10.2.2 and Table 4.10-4.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	268	<p>“The most likely impact of the SGP on this subpopulation would be dust associated with construction of the West End Creek diversion, which could travel upslope and impact this subpopulation or its pollinators.” Please take into consideration dust control measures, the small project size of a diversion project, and the proximity of the diversion (300ft or more) to the noted sub-population.</p>	VEG	No text revisions made. Due to the proximity of the known subpopulation and the sensitivity of this species to disturbance, despite design features and protection measures implemented during the Project, the statement regarding potential impacts is accurate.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	269	<p>“Impacts of dust on the Cinnabar Peak subpopulation could range from mild metabolic inhibition or inhibition of pollination to mortality of individuals; dust also could inhibit pollination success.” Please provide a reference for this statement.</p>	VEG	Text has been added per the comment.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	270	<p>“The combination of these potential impacts would result primarily in localized, long-term and permanent, moderate impacts to the bent-flowered milkvetch.” Please explain how these effects are permanent. Please explain how the effects are moderate instead of minor. The next statement says indirect impacts and only one individual, so please explain how can these be an easily measurable change and readily noticeable.</p>	VEG	Text has been revised per the comment. Additional detail regarding the potential impacts to the species based on the available occurrence data has been added to this section.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	271	<p>“(one out of a total of approximately 653 individuals within 10 populations identified on the PNF)” Please clarify and provide a methods summary, reference, and context of how these numbers were calculated. Also include a percentage of the greater whole for context.</p>	VEG	Text has been revised per the comment. Additional detail regarding the potential impacts to the species based on the available occurrence data has been added to this section.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	272	<p>“The combination of these potential impacts would result primarily in localized, long-term and permanent, moderate impacts to the least moonwort.” Please correct this statement as it is in error under the MMP alternative because the JC Road would only be utilized for up to 3 years during the</p>	VEG	Text has been revised per the comment.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Resources Idaho, Inc.)			construction period. Therefore, by definition (table 4.1-1) these impacts would be classified as short-term.		
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	273	“ The combination of these potential impacts would result primarily in localized, long-term and permanent, moderate impacts to the least moonwort.” This statement is used for every species, but it needs more supporting statements. Please explain this statement. Please explain how these effects are permanent. Please explain how the effects are moderate instead of minor. The next statement says indirect impacts and only two individuals, so please explain how can these be an easily measurable change and readily noticeable.	VEG	Text has been revised per the comment. Additional detail regarding the potential impacts to the species based on the available occurrence data has been added to this section.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	274	“ (two out of a total of approximately 1,731 individuals in 14 populations on the PNF) ” Please clarify and provide a methods summary, reference, and context of how these numbers were calculated. Also include a percentage of the greater whole for context.	VEG	No text revisions made. This statement is accurate based on the known locations of the species and potential impacts based on the 2021 MMP.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	275	“ Increased dust deposition could result in impacts ranging from metabolic inhibition to mortality of individuals. ” Please provide a reference	VEG	Text has been revised per the comment.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	276	“ Therefore, the 2021 MMP may indirectly impact Blandow’s helodium individuals (one) ” Please clarify and provide a methods summary, reference, and context of how these numbers were calculated. Also include a percentage of the greater whole for context.	VEG	No text revisions made. This is the only occurrence of the species on the PNF and BNF and the analysis is accurate on potential impacts based on the 2021 MMP.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	277	“ Table 4.10-4 Acres of Direct Impacts to Modeled Special Status Plant Potential Habitat under the 2021 MMP” For clarity, we suggest changing the title of this table to” Acres of Modeled Special Status Plant Potential Habitat within the 2021 MMP Disturbance Footprint” .	VEG	Text has been revised per the comment.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	278	“ Table 4.10-5 Total Acres of Disturbance to Vegetation Communities due to SGP Components under the 2021 MMP” For clarity, we suggest changing the title of this table to” Total Acres of Vegetation Communities within the 2021 MMP Disturbance Footprint”	VEG	Text has been revised per the comment.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	279	Please clarify how these numbers were calculated and what datasets were used.	VEG	Text has been revised per the comment.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	280	Overall total acres in table is 3,563.7 . Please check the numbers in this table and clarify how and why this total acreage of disturbance is more than the total acreage of disturbance reported in Chapter 2 (Table 2.4-1; 3,265.9).	VEG	No text revisions made. This acreage includes acres associated with the potential maximum extent of tall tree clearing associated with the power line.

Resources Idaho, Inc.)					
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	281	“ <i>Table 4.10-6 Acres of Disturbance to Previously Undisturbed Forested PVGs under the Johnson Creek Route Alternative</i> ” For clarity, we suggest changing the title of this table to” Acres of Previously Undisturbed Forested PVGs within the Johnson Creek Route Alternative Disturbance Footprint ”	VEG	Text has been revised per the comment.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	282	“ <i>Table 4.10-7 Acres of Disturbance to Areas Identified as not Successional to Forested PVGs under the Johnson Creek Route Alternative</i> ” For clarity, we suggest changing the title of this table to” Acres of Areas Identified as not Successional to Forested PVGs within the Johnson Creek Route Alternative Disturbance Footprint ”	VEG	Text has been revised per the comment.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	283	“ <i>Table 4.10-8 Acres of Disturbance to Vegetated Acres Outside Forest Service-Managed Lands under the Johnson Creek Route Alternative</i> ” For clarity, we suggest changing the title of this table to” Acres of Vegetation outside of BNF and PNF - Managed Lands within the Johnson Creek Route Alternative Disturbance Footprint. ” SCNF lands are included in these calculations.	VEG	Text has been revised per the comment.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	284	“ <i>The impacts to the Bent-flowered Milkvetch and Sacajawea’s Bitterroot under the Johnson Creek Route Alternative are the same as described for the 2021 MMP.</i> ” Please add a clarifying summary statement about the one species discussed below: least moonwort.	VEG	Text has been added per the comment. “Impacts to the least moonwort are discussed below.” has been added following the statement regarding bent-flowered milkvetch and Sacajawea's bitterroot.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	285	“ <i>The Johnson Creek Route Alternative could impact subpopulations of the occurrence of least moonwort in the same manner as described under the 2021 MMP.</i> ” Please provide a short summary or description of what those impacts are.	VEG	No text revisions made. Impacts are discussed under the 2021 MMP and the reader is referred to that section of the analysis.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	286	“ <i>However, due to the localized nature of impacts within roadside swales under the Johnson Creek Route Alternative, impacts to this species may be greater than under the 2021 MMP.</i> ” Please clarify and support this statement.	VEG	Text has been added per the comment.” This is primarily due to this species often occurring in ditches and roadside swales in areas near historic disturbance.” has been added to this section.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	287	“ <i>Table 4.10-10 Total acres of Disturbance to Vegetation Communities due to SGP Components under the Johnson Creek Route Alternative</i> ” Please check the numbers in this table and clarify how and why this total acreage of disturbance (3,399.3) is more than the total acreage of disturbance reported in Chapter 2 (Table 2.5-2; 3,095.2).	VEG	No text revisions made. As described in the Vegetation Specialist Report, this total acreage includes the maximum possible extent of tall tree clearing as well associated with the power line.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	288	“ <i>At this time, no mitigation measures have been identified for Vegetation.</i> ” This statement is inconsistent with Table 2.4-12 (and Table 2-2 of the Vegetation Specialist Report) which includes measures that are applicable to vegetation per the” Resources Affected” column. Please amend this sentence to reflect these measures.	VEG	Text has been added regarding mitigation measures required by the Forest Service, primarily for whitebark pine.

Resources Idaho, Inc.)					
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	289	“ <i>Alternative are renewable only over long-time spans, including mature vegetation, special status plants, seedbanks, and topsoil. Loss of these resources would be considered irreversible.</i> ” Please delete” Loss of these resources would be considered irreversible.” Renewable over long-time spans is by definition not irreversible.	VEG	No text revisions made. The term” irretrievable” is appropriate here as the loss of vegetation/soils resources would make those resources not available or present during the Project until reclamation is complete and likely much later.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	290	“ <i>This includes the loss of soil resources; even with reclamation (Tetra Tech 2021a), the temporal loss of the resource is irretrievable.</i> ” Please double check this reference as it does not characterize loss of soil resources as irretrievable.	VEG	No text revisions made. The term” irretrievable” is appropriate here as the loss of soil resources would make those soils not available during the Project until reclamation is complete. The Tetra Tech 2021 reference is referring to the reclamation plan, not the irretrievable statement.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	291	“ <i>Construction and operation of the mine could also affect long-term vegetation productivity by increasing sedimentation from erosion and increasing the amount of pollutants and fine-grained sediments delivered to the area via surface water runoff.</i> ” Please delete this statement. This statement does not account for the restoration of Blowout Creek early in the project and does not take into consideration all of the sediment control environmental design features built into the MMP.	VEG	Text has been deleted per the comment.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	292	“ <i>Detailed calculations of impacts to whitebark pine occupied habitat and individual trees are reported in Appendix F</i> ” Please clarify and provide a methods summary, reference, and context of how these estimated WBP numbers were calculated. These discrete reported numbers are derived from very broad estimates and categories from field surveys and not an actual count of individuals.	VEG	Appendix F of the Vegetation Specialist Report contains details of the calculations in the footnotes for Table F-1 and Table F-2. Additionally, text has been added per the comment regarding the” estimate” of whitebark pine resources during the field survey in 2019 conducted by TetraTech.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	293	“ <i>The 2021 MMP would impact 3,991.0 acres of modeled potential habitat for sensitive and forest watch plant species. The Johnson Creek Route Alternative would impact 3,203.6 acres of modeled potential habitat for sensitive and forest watch plant species.</i> ” and” <i>The Johnson Creek Route Alternative would impact 3,203.6 acres of modeled potential habitat for sensitive and forest watch plant species.</i> ” Please check and clarify how these numbers of acres are larger or nearly so than the total acres of vegetation cleared in the rows below. Providing a total number of acres of modeled potential habitat results in double counting areas that are considered potential habitat for multiple species. Please correct.	VEG	Text has been revised to only include a range of acreages for the various sensitive and forest watch plants species and not a total acreage. This should clear up any confusion on” double counting” potential impact areas.
Alan Haslam (Vice President, Permitting, Perpetua Resources Idaho, Inc.)	19325	11	Comments on SDEIS Sections 3.10, 4.10 and the Vegetation Specialist Report include requests for missing or updated references and clarification on descriptions of the effects analysis. Also, review of other resource analyses and the Vegetation resource in particular (Section 4.10.5.2) note that:” Construction and operation of the mine could also affect long-term vegetation productivity by increasing sedimentation from erosion and increasing the amount of pollutants and fine-grained sediments delivered to the area via surface water runoff.” Here and elsewhere in the SDEIS (e.g., Fisheries and Water Quality), statements such as these on potential impacts from increased sedimentation do not appear to account for (and do not describe or adequately describe) the restoration of Blowout Creek early in the Project, nor do they take into consideration all of the sediment control environmental design features built into the 2021 MMP. Reclamation of Blowout Creek in particular should be considered in impacts analysis in both the short- and long-term for applicable resources as it addresses what has been identified as the single largest sediment generator in the upper East Fork of the South Fork of the Salmon River drainage.	VEG	No text revisions made. Section 4.9 discusses sedimentation in detail in relation to reclamation along Blowout Creek.
Jesse Lutz	19386	15	Availability of information - For reasons of inadequate availability of information to the public, I am requesting that this proposal should be at least reevaluated again from the start or even better - denied. Examples are as follows - concerning Air Quality * recently updated to public viewing in November and	VEG	Text has been revised per the comment to update the status of the whitebark pine per the listing on December 15, 2022. Additionally, the analysis and required protection measures as

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>December - quite some time after public commenting was already open, White Bark Pine Survey information dated in 2020 *recently updated to public viewing Pinyon application on December 30th - NOTE the most recent designation as a threatened species on National Forest Lands by US Fish and Wildlife service (https://www.fws.gov/pressrelease/2022-12/whitebark-pine-receives-esa-protection-threatened-species) which would require further biological assessments and research to determine the final level of impacts that proposed operations would introduce during the lifespan of the project (up to 40 years including 'reclamation', 'restoration', and 'further monitoring activities') Please remember, and take seriously, the associated impacts that will be left behind on our tribal and public lands that we all steward as citizens of this country) Please find these quotes helpful in your reflections and reevaluations on the impacts of the proposed action to permit this Gold Mine - again for these reasons this proposal should be reevaluated from the start or be denied in its current form.</p> <p>“ Whitebark pine is the center of an important web of life and provides valuable ecosystem services in western high-elevation forests.” said Diana Tomback, Whitebark Pine Ecosystem Foundation policy and outreach coordinator and professor of integrative biology at the University of Colorado Denver.” But it is facing an unprecedented convergence of lethal threats. We have the tools and capability to make populations more resilient to these threats. Given the scale of this effort, we are approaching restoration both collaboratively and strategically. One promising work in progress is the National Whitebark Pine Restoration Plan, a roadmap for restoration being developed collaboratively between the Whitebark Pine Ecosystem Foundation and American Forests, in consultation with the US Forest Service, the National Park Service, Bureau of Land Management, and several northwestern tribes.”</p> <p>“ The Confederated Salish and Kootenai Tribes' of Montana commend and honor the USFWS decision listing Whitebark pine as a threatened species, said the Confederated Salish and Kootenai Tribes Forestry Department.</p> <p>“ Native Americans continue to be stewards of the land and understand the need for balanced ecosystems. CS&KT does this by utilizing our traditional ecological knowledge taught from story and songs and applying it to western science techniques. Whitebark pine is not only a keystone species for this balance, but it is also part of our first foods and culture. CS&KT supports the listing Whitebark pine to help ensure the protection and restoration of the land and of our culture.”</p> <p>Keystone species are labeled as keystones for the reason - that if they did not exist or are impacted beyond healthy ecological and biological levels that are unstable then other species follow.</p> <p>Can you please elaborate on how the USFS intends to reevaluate managing this designation considering the negative impacts? Net loss; which is shown in this proposal would degrade the current habitat conditions which exist in the proposed project area. This is connected to the air quality impacts on natural species that require consistently clean air. I would like to ask this - What impacts to White Bark pine and other tree types will be seen in 10-year increments for up to 100 years after mining operations cease?</p>		well as mitigation measures required by the Forest Service have been added to the Final EIS, specifically in Sections 3.10, 4.10, and 5.10, as appropriate.
Jesse Lutz	19386	17	Have there been any studies to show the expanse of acid rain impacts from particulate pollutants released during operations - if not can you please provide this to the public? This information would assist the public in seeing long-term impacts from the proposed mining operation to the varying tree types found throughout the area of concern.	VEG	No text revisions made. The Project is not expected to result in increased acid rain during operations.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	175	Additionally, neither the SDEIS nor SGP Vegetation Specialist Report discusses the impacts of avalanche control on whitebark pine. Avalanche control work has the potential to artificially trigger avalanches that would not otherwise have occurred and therefore destroy or damage whitebark pine. It is not clear that whitebark pine surveys conducted by Perpetua included individuals living within avalanche starting zones, tracks, or runouts. The SDEIS should ensure that all species members impacted by SGP activities are accounted for in these surveys. Artificially triggering avalanches, while beneficial for decreasing risk that vehicles will be struck, may also incidentally take whitebark pine individuals. This impact should also be addressed.	VEG	No text revisions made. Avalanche control would only occur in areas that are already prone to avalanches and where avalanches occur naturally. Therefore, it is unlikely these areas support whitebark pine populations.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	177	<p>M. Utilities, rights-of-way, roads, and routes</p> <p>The construction and long-term operation associated with transmission line upgrades causes serious impacts, including direct damage to wildlands, wildlife habitat and cultural resources, interference with scenic vistas, habitat fragmentation, the introduction of invasive and noxious weeds through ground disturbing activities, and others. Much of the landscape in Idaho, even near streams, has been visually impacted by human features such as roads, structures, transmission lines, and other infrastructure. The SGP would require Idaho Power to build four new electrical substations (Scott Valley, Thunderbolt Tap, Johnson Creek, and Stibnite), remove the existing Scott Valley Substation, and provide upgrades to the Cascade Switching Station (SDEIS, p. 2-23). Direct and indirect impacts to the SGP-related transmission lines, related access roads, utilities and their infrastructures are represented as equitable between the 2021 MMP alternative and the Johnson Creek alternative, with 1012 acres of disturbed lands under the former and 1011 acres under the later alternative (SDEIS, Table ES-2).</p> <p>Additional electrical changes include rerouting power to the village of Yellow Pine from the Warm Lake substation to the Johnson Creek substation, upgrading nearly 64 miles of existing transmission lines with higher towers, transformers and line, and constructing an additional 8.5 miles of new transmission line from the Johnson Creek substation to the mine site. Further, Perpetua Resources proposes to upgrade microwave relay towers and install radio repeaters and cell phone towers at existing and new communication sites on public and private lands. Transmission line right-of-way (ROW) widths would range from 50 to 100 feet, requiring significant additional initial vegetation removal, with continual vegetation removal as part of long-term maintenance of these clearings. Both the 2021 MMP alternative and the Johnson Creek Route alternative will result in 422 acres of impacts within the identified ROWs in previously undisturbed areas (SDEIS, Table ES-3, p. ES-22).</p> <p>Approximately one-third of the transmission line ROW is found within forested areas, and the Forest Service estimates that, "SGP-related vegetation clearing could initially result in (Detrimental Disturbance) as high as 16 percent of the ROW," and would likely impact somewhere between 8 and 15 percent (SDEIS, p. 4-83-84). These impacts, consisting primarily of vegetation clearing, but also including soil disturbance for access roads, line upgrades, and construction of new line pole foundations, will take place on an estimated 500 acres. The duration of these impacts are considered, "moderate, localized and long-term," (SDEIS, p. 4-84), with disturbance beginning the first year of construction and continuing at least through Year 15. Furthermore, clearing activities would continue indefinitely on upgraded line corridors by Idaho Power Company after mining activities cease. The loss of these vegetation communities and impacts associated with access roads for construction and subsequent maintenance represent irreplaceable and irretrievable impacts to natural resources found on public lands, and therefore neither the 2021 MMP, nor the Johnson Creek Route alternative are appropriate selections for the SGP.</p>	VEG	No further response required. General in nature or position statement.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	178	<p>On December 14, 2022, the US Fish and Wildlife Service announced its decision to list whitebark pine as a threatened species under the Endangered Species Act. This rule is to become effective starting January 17, 2023. The Forest Service will have to consult on expanding and constructing Rights-of-Way. Our specific comments pertaining to whitebark pine are found in Section R, Botanical Resources.</p>	VEG	Text has been revised per the comment to update the status of the whitebark pine per the listing on December 15, 2022. Additionally, the analysis and required protection measures as well as mitigation measures required by the Forest Service have been added to the Final EIS, specifically in Sections 3.10, 4.10, and 5.10, as appropriate.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	190	<p>4. Invasive grasses and noxious weeds</p> <p>According to the Special Designations Specialists Report (SDSR) there will be 740 acres of vegetation removed within six IRAs to construct transmission lines, access roads, SGP facilities, and to construct the proposed Burntlog Route. This represents a significant opportunity for non-native plant species, particularly invasive plants and noxious weeds, to establish and create or expand unwanted vegetation populations. The SDSR supports this statement on page 78 where it states that, "Areas within IRAs where non-native plant species become established would alter vegetation composition and change the natural ecological processes." Mitigation includes BMPs for invasive plants and noxious weeds, with monitoring for 3 years following the reseeding and planting of disturbed areas. However, we do not believe this is sufficient considering the decades worth of continued maintenance and use these ROWs</p>	VEG	No text revisions made. The Forest Service has reviewed the existing BMPs and design features, as well as the RCP, and determined that the current list is adequate.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>and facility locations would require to establish and maintain protections against wildfire and access. In fact, the SDSR reinforces our concerns where it states that, "Maintaining the new transmission line, SGP facilities, and Burntlog Route during the 15 years of mine operation would increase the opportunities for non-native plant species distribution," (Special Designations Specialists Report, p. 78). We recommend that the Forest Service reexamine existing BMPs and Design Features and extend monitoring for noxious and invasive plant species throughout the life of the project in all areas of disturbed soils and vegetation, including closure and reclamation.</p> <p>One of the most significant threats to any ecosystem remains the introduction of invasive grasses and noxious weeds associated with ground disturbing activities. We encourage the Forest Service/Perpetua to use integrated weed treatment methods. To the extent practical, herbicides should only be used as a last resort and avoided in sensitive areas such as riparian areas or areas with rare plant populations. Lands treated for noxious weeds should be restored to native plant species when possible. Preserving and restoring intact soil layers represents the best way to avoid invasive plant and noxious weed introduction. Therefore, we recommend disturbing as little soil as possible. This becomes especially poignant when the Forest Service takes into consideration the fact that very little topsoil, or growth media, is available within the project area and it is unlikely that enough can be preserved and stored to sufficiently facilitate the establishment of riparian areas during the reclamation period (SDEIS, Executive Summary, pp. 11-12).</p> <p>We are concerned that soil disturbance can lead to the establishment of rush skeleton weed, spotted knapweed, dalmatian toadflax, and other noxious weeds. Newly constructed or modified rights-of-way associated with anthropogenic infrastructure also contribute to the spread of non-native plants. The disturbance needed to upgrade existing transmission lines, construct new transmission line segments, to upgrade existing roads and to build new road segments like the proposed Burntlog Route provides an ideal vector for noxious weed expansion. The Forest Service/Perpetua needs to take far greater care to ensure that weed spread is minimized, particularly to special designations such as IRAs, the Chilcoot Peak Research Natural Area and the FCRNRW.</p>		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	191	<p>5. Transmission lines and wildfires</p> <p>Numerous fires have started from transmission lines and the Forest Service needs to disclose those potential risks and ways to avoid, minimize, and mitigate these risks. Methods to minimize the risk of fires often involve establishing a wider ROW corridor, removing vegetation from a wider area, and conducting more frequent vegetation clearing. These fuel reduction measures will exacerbate the habitat fragmentation from ROW establishment and expansion. The Forest Service needs to evaluate the effects of both the transmission lines and maintenance activities and develop mitigation strategies.</p> <p>Transmission lines can also be burned over in wildfires, leading to power failures. Because of the long distance of this transmission line, there will be numerous ways for power to be interrupted. In addition to wildfires, other mechanisms include vehicle crashes, avalanches, landslides, and wind storms</p>	VEG	No text revisions made. Section 4.21.2.2 (Socioeconomics) discusses the potential increase in human-caused fire associated with the Project. Additionally, Perpetua proposes tree clearing along the transmission line ROW as a way to reduce the potential for trees to fall on the transmission line and thus creating a fire hazard.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	276	<p>R. Botanical Resources</p> <p>1. Sensitive and Forest Watch Plant Species</p> <p>While the SDEIS provides a largely accurate description of the botanical resources in the analysis area, some of the surveys are out of date and do not represent an accurate baseline survey. In addition, the SDEIS falls short in describing both the direct and indirect impacts to these botanical resources and does not take the requisite "hard look" at impacts to these species. The SDEIS quantifies how many acres will be disturbed, but it does not go into sufficient detail on what the impact of these disturbances will be for each sensitive species or its ecology. For most sensitive plants, any disturbance is a negative impact. There are a large number of habitat disturbing, degrading, and destroying activities proposed as part of this project, including road construction, drainage construction, ROW expansion, additional exploration activities, dust generation, and extensive earth moving within the mine footprint. Roads and other habitat</p>	VEG	No text revisions made. Occurrence data for sensitive and watch species has been provided and are still accurate for the analysis. Additionally, details regarding potential impacts to sensitive and watch species is provided in Section 4.10.2 and measures proposed by Perpetua and required by the Forest Service, primarily the requirement of preconstruction surveys to identify occurrences of sensitive and watch species and then establish protection measures, would reduce Project-related impacts to these species.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>clearing activities can cause a direct loss of individual plants. Roads and ditches can alter groundwater and surface water flows and affect surrounding vegetation communities accordingly.</p> <p>Roads also lead to increased wind speed and drying effects from vegetation removal and are also associated with an increased risk of human-caused wildfires. Roads can also increase dust which may reduce photosynthesis rates for remaining vegetation. Roadside spills of hazardous chemicals can affect soils and vegetation. In addition, there may be increased contaminants of concern in dust from mine traffic which may in turn affect soils, plants, animals and human health. Increased salt levels in the soil from magnesium chloride application that can negatively affect vegetation.</p> <p>In addition to direct habitat loss from project activities, roads and traffic can serve as vectors for the introduction of non-native plant species that may outcompete native species. The SDEIS makes a nod toward this with the following statement:</p> <p>However, even with strict adherence to noxious weed and non-native plant species control measures, some colonization, and spread of noxious weeds and non-native species in and adjacent to the Stibnite Gold Project area is possible.</p> <p>This above statement is a major understatement. It is beyond” possible.” It is extremely likely that exotic plants will dominate the disturbed sites.</p> <p>Areas with roads and transmission lines are known vectors for noxious weed infestations that can threaten native plants. The Forest Service needs to conduct a detailed analysis in the Supplemental SDEIS of specific exotic species that may become established in the project area and describe the potential direct and indirect effects to native species. Based on the habitat types and history of disturbance in a similar roadbed area, the Forest Service could predict the species of exotic plant that might dominate and how that might impact the overall ecology of these ecosystems. Yet, the Forest Service has not surveyed or mapped these infested areas in the detail proscribed in the Forest Plan: Objective BTOB08 During fine- and site/project-scale-analyses, identify and map areas of non-native plant invasions within rare plant habitat.</p>		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	277	<p>In addition to impacts related directly to the Stibnite Gold Project, additional exploration activities in the project area will also have impacts. From the SDEIS: These approved activities include construction of several temporary roads (approximately 0.32 mile of temporary roads) to access drill sites (total of 28 drill sites), drill pad construction (total of 182 drill pads) and drilling on both NFS and private lands at and in the vicinity of the SGP. SDEIS p. 4-33.</p> <p>These temporary roads do not appear to be accounted for in the acres of disturbance.</p> <p>These exploration roads are part of the cumulative effect to this project and should be included in the Supplemental SDEIS. Backfilling sites with disturbed soils and recontouring are likely to result in these areas turning into weed patches. The Forest Service should create plans and funding sources to replant disturbed areas with native plants and have contingency plans and funds until native vegetation has recovered. The Forest Service should also establish a long term monitoring program for the twenty years following mine closure along with funding to replant areas as needed.</p>	VEG	No text revisions made. The exploration activities are already included in the acreage for the Project, primarily at the mine site. Additionally, all disturbed areas would be treated to prevent the establishment of noxious weeds and reclaimed according to requirements by the Forest Service. Bonding would be established to ensure proper reclamation as a result of the Project takes place.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	278	<p>The project’s impacts on botanical resources are anticipated to be regional in scale, as opposed to localized due in large part to the large amount of disturbance and increased potential for non-native plant expansion of both alternatives. Each alternative would impact botanical resources, with the 2021 MMP impacting a larger amount of occupied and potential habitat:</p> <p>The 2021 MMP would impact known occurrences of bent-flowered milkvetch, least moonwort, Sacajawea’s bitterroot, Blandow’s helodium, sweetgrass, and Rannoch-rush, while the Johnson Creek Route Alternative would impact known occurrences of bent-flowered milkvetch, least moonwort, and Sacajawea’s bitterroot. Additionally, the 2021 MMP would impact a greater amount of modeled potential habitat (3,991 acres) for sensitive and forest watch plant species than the Johnson Creek Route Alternative (3,204 acres). (ES-16).</p>	VEG	No text revisions made. Details regarding potential impacts to sensitive and watch species is provided in Section 4.10.2 and measures proposed by Perpetua and required by the Forest Service, primarily the requirement of preconstruction surveys to identify occurrences of sensitive and watch species and then establish protection measures, would reduce Project-related impacts to these species.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>A species-specific impact analysis does not seem to exist. The Forest Service merely provides a table comparing the number of acres disturbed. Table 4.10-9” Acres of Modeled Potential Habitat for Special Status Plants Directly Impacted under All Action Alternatives” provides a good comparison to the extent of disturbance between alternatives but there is no analysis of what those impacts are to the vegetation types or to the individual sensitive plant species.</p> <p>The Forest Service did not appear to have prioritized efforts to avoid, minimize and mitigate for impacts to botanical resources and mostly minimized the importance of any rare plant subpopulations that could be impacted or extirpated:</p> <p>There are no known plant-based subsistence resources located exclusively within the Operations Area Boundary that are not available on the remaining portions of the PNF. (SDEIS 4-673).</p> <p>However, this dismissive approach contradicts several Forest Plan goals, guidelines, objectives and standards as detailed below. Both Sacajawea’s bitterroot and least moonwort are Forest Service sensitive species, which are supposed to be managed so that there is no population trend that could lead to a listing decision:” may impact individuals, but would not likely contribute to a trend toward federal listing or loss of viability of populations or species.” SDEIS 4-301. Forest Watch species are species of concern that need to be monitored and include bent-flowered milkvetch, Blandow’s helodium, sweetgrass and Rannoch-rush. All six species occur within or adjacent to the area of analysis.</p>		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	279	<p>a. Sacajawea’s bitterroot (Sensitive Species)</p> <p>Sacajawea’s bitterroot (Lewisia sacajaweanana or” LESA”) is” the highest priority rare plant species managed by the Boise National Forest.” CU084004. In 2011, the Forest Service designated Sacajawea’s bitterroot as a” Priority Forest Watch Species.” The Forest Service has since reclassified this plant as a sensitive species. There are only 30 known occurrences of subpopulations with most populations numbering less than 2,000 individual plants. The Boise National Forest hosts approximately eighty percent of the entire population.</p> <p>There is an isolated occurrence of Sacajawea’s bitterroot in the project analysis area along Warm Lake Road: One occurrence of Sacajawea’s bitterroot, a Forest Service sensitive species on both the PNF and BNF, occurs approximately 300 feet above Warm Lake Road (CR 10-579) and the existing transmission line corridor near the intersection of Warm Lake Road with Curtis Creek Road (IFWIS 2017) in the BNF. This occurrence is on a hillside above a portion of Warm Lake Road, and the polygon for this occurrence overlaps a transmission line access road that would be used during transmission line reconstruction and SGP operation. Spur road construction and use of this dirt road during transmission line reconstruction and SGP operation would create dust that could negatively impact this occurrence of Sacajawea’s bitterroot. Impacts of dust on this species could range from mild metabolic inhibition to mortality of individuals.</p> <p>The combination of these potential impacts would result primarily in localized, long-term and permanent, moderate impacts to the Sacajawea’s bitterroot. Therefore, the 2021 MMP may indirectly impact Sacajawea’s bitterroot individuals (one out of approximately 157,023 individuals in 27 populations on the PNF) and habitat but would not likely contribute to a trend towards ESA listing or loss of viability of the species within the planning area (i.e., BNF-administered lands).(SDEIS p. 4-293-294).</p> <p>The SDEIS refers to direct impacts on one individual out of an estimated 157,023 individuals in 27 populations. The cited number appears to be an overestimation of the population. The SDEIS mentions one individual plant when the Forest Service may have meant one population. There are also cultural implications: While offsite presence of plants means the impact to overall access to a specific type of plant would be negligible to minor, this would still constitute a localized, long-term, and moderate to major impact to tribal treaty rights specific to those resources in their specific locations including those associated with potential historic properties, sacred sites or places, TCPs, and CLs. (SDEIS 4-680).</p>	VEG	No text revisions made. Occurrence data for sensitive and watch species has been provided and are still accurate for the analysis. Additionally, details regarding potential impacts to sensitive and watch species is provided in Section 4.10.2 and measures proposed by Perpetua and required by the Forest Service, primarily the requirement of preconstruction surveys to identify occurrences of sensitive and watch species and then establish protection measures, would reduce Project-related impacts to these species.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>The largest Sacajawea’s bitterroot population is found in the Boise National Forest within the project area of the CuMo Mine Exploration Project, approximately 50 miles to the south of the Warm Lake population. When permitting mine exploration for the CuMo Project, the Boise National Forest took some additional steps to protect the plant population by designating a Plant Conservation Areas around occupied habitat. The Forest Service also determined that protecting pollinator habitat within and adjacent to occupied habitat was” essential to the long-term persistence of the species” and included a 300-meter buffer intended to include pollinator habitat. CU084021. 12.</p> <p>The Boise National Forest acknowledged that road and drill pad construction, road maintenance and other ground disturbing activities can” further destroy and degrade habitat and plants by crushing or uprooting plants, depositing slash or debris on plants, spreading exotic weeds, changing hydrology and exposure, causing mortality from soil disturbance and compaction, and depositing dust on plants and pollinator habitat.” CU084020.</p> <p>As part of the CuMo Mine Environmental Assessment, the Boise National Forest determined that most of Sacajawea’s bitterroot habitat at the CuMo Project site was” highly susceptible” to invasion by noxious weeds. CU084014. Furthermore, the Boise National Forest determined that the species is highly vulnerable to climate change as” any future rise in snowline could impact the viability of this population” (CU084013). This population's small relative size and lack of genetic diversity limited its ability to adapt and respond to disturbance. CU084010–11. The Boise National Forest determined that the limited genetic diversity” further underscore the need to protect potential and occupied LESA habitat to the greatest degree possible.” CU084011. 14. Such small populations are at risk of extirpation from stochastic events including human disturbance.</p> <p>The Boise National Forest attempted mitigation efforts to avoid and reduce impacts to the greatest extent practicable. (CU045833, 0457880.) For example, where new infrastructure such as road or drill pads was proposed near plants, there would be an effort to relocate these structures and also schedule activities to avoid the main period of growth and reproduction for the plant.</p> <p>There are a number of places where the SDEIS deviates from the Boise and Payette Forest Plans with regard to these botanical resources.</p> <p>For example, no recent surveys have been conducted for this population of Sacajawea’s bitterroot: This occurrence was last observed in 1999 and has an unknown number of individuals (IFWIS 2017). This occurrence was not documented by surveyors in 2014 although this species was targeted during surveys that year (HDR 2017g).(SDEIS 3-229)</p> <p>This lack of analysis is inconsistent with Boise National Forest Plan Objectives BTOB01 and BTOB02: Objective BTOB01: Continue to map locations of suitable occupied habitat for Region 4 Sensitive plant species, Forest Watch plants, and globally rare plant communities. Incorporate information into a GIS database and coordinate with the Idaho Conservation Data Center.</p> <p>Objective BTOB02: During fine-scale analyses in areas containing sensitive species habitat, identify and prioritize opportunities for restoring degraded Sensitive species habitat.</p>		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	280	<p>There are likely to be adverse permanent effects to this population of Sacajawea’s bitterroot from the transmission line upgrades, spur road construction, dust generation, and noxious weed spraying along the ROW. This discretionary degradation of habitat is inconsistent with the Forest Plan Standards and Goals: Standard BTST01 Management actions that occur within occupied sensitive plant species habitat must incorporate measures to ensure habitat is maintained where it is within desired conditions, or restored where degraded.</p> <p>Goal BTGO03 Maintain or restore globally rare plants identified as the Natural Heritage Program G1, G2, and G3 and/or S1 and S2 species, and provide for their continued compositional and functional integrity for those species for which we have habitat (see Appendix C).</p>	VEG	No text revisions made. Details regarding potential impacts to sensitive and watch species is provided in Section 4.10.2 and measures proposed by Perpetua and required by the Forest Service, primarily the requirement of preconstruction surveys to identify occurrences of sensitive and watch species and then establish protection measures, would reduce Project-related impacts to these species.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			The Forest Service needs to consider an alternate alignment of the transmission line in this location as well as location of the spur roads to make sure that Sacajawea's bitterroot and its habitat is made more secure.		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	282	<p>While noxious weed spraying should be considered along roads and rights of way, noxious weed spraying efforts should be modified in the transmission line corridor near the population of Sacajawea's bitterroot, per Forest Plan standards and guidelines: Standard BTST04 For projects or activities that include application of insecticides, herbicides, fungicides, or rodenticides, degrading effects on sensitive plant species will be mitigated.</p> <p>Guideline BTGU02 During site/project-scale analysis and review, a Forest botanist should review insecticide or herbicide spray plans and prescribed burning plans to determine whether degrading effects to Sensitive and Forest Watch plants and their pollinators should be mitigated. We recommend that the Forest Service resurvey Sacajawea's bitterroot during the appropriate time of the next field season, reestablish the baseline, and adopt additional design features to avoid, minimize and mitigate impacts to this species.</p>	VEG	No text revisions made. Details regarding potential impacts to sensitive and watch species is provided in Section 4.10.2 and measures proposed by Perpetua and required by the Forest Service, primarily the requirement of preconstruction surveys to identify occurrences of sensitive and watch species and then establish protection measures, would reduce Project-related impacts to these species.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	283	<p>b. Bent-flowered milkvetch (Forest Watch Species)</p> <p>Although bent-flowered milkvetch is ranked as globally secure, it is extremely uncommon in Idaho where it receives a ranking of S1: 1 = Critically imperiled — Typically having five or fewer occurrences, or 1,000 or fewer individuals.</p> <p>The largest population in the entire state of Idaho is located approximately 300-1,500 feet west of the West End Creek diversion: Five subpopulations of a single occurrence (the Cinnabar Peak occurrence) of this species were documented during surveys in 2012, 2013 (HDR 2017g), and 2016 (Mancuso 2016, IFWIS 2017). The nearest subpopulation of the Cinnabar Peak occurrence extends from about 300 feet to one-quarter mile upslope from and to the east of the West End Creek diversion. This subpopulation, which consists of an estimated total of 7,000 to 10,000 plants, is about 25 acres in size and is located in a relatively undisturbed area. (SDEIS 3-228).</p> <p>In addition, 122 acres of potential habitat has been modeled near the Operations Area Boundary, transmission line and Meadow Creek Lookout Road. It is unclear if these areas have been surveyed. This subpopulation is the largest contiguous area of occupied habitat for this species in Idaho and is considered to be critical to the long-term viability of this species, as it could serve as seed sources for future conservation efforts.</p> <p>Although the bent-flowered milkvetch has been found in historically disturbed sites, a recent report on the species notes the importance of undisturbed areas: Although present in disturbed locations, the long-term persistence of bent-flowered milkvetch near Cinnabar Peak may depend on plants located in areas of intact, minimally disturbed-undisturbed habitat that can serve as seed source reserves. Depending on the location and scale of future ground disturbances associated with the Stibnite Gold Project in the area, seeds from these reserves may be critical for post-disturbance re-establishment of bent-flower milkvetch into formerly occupied areas. (Field Survey for Bent-Flowered Milkvetch in the Stibnite Gold Project Area, Valley County, ID Michael Mancuso 2016).</p> <p>The SDEIS highlights the impacts of dust generation on bent-flowered milkvetch which are located downwind of project activities: The 2021 MMP could impact the Cinnabar Peak subpopulation due to its proximity to the West End Creek diversion. The most likely impact of the SGP on this subpopulation would be dust associated with construction of the West End Creek diversion, which could travel upslope and impact this subpopulation or its pollinators. Impacts of dust on the Cinnabar Peak subpopulation could range from mild metabolic inhibition or inhibition of pollination to mortality of individuals; dust also could inhibit pollination success. These impacts may result in reduced ability of this subpopulation to serve as a seed source for future conservation efforts for this species. The area of potential exploratory drilling overlaps with subpopulations of this species. Exploratory drilling within this area has the potential to impact this species directly through removal or crushing and/or via dust deposition or impacts to pollinators. The combination of these potential impacts would result primarily in localized,</p>	VEG	No text revisions made. Details regarding potential impacts to sensitive and watch species is provided in Section 4.10.2 and measures proposed by Perpetua and required by the Forest Service, primarily the requirement of preconstruction surveys to identify occurrences of sensitive and watch species and then establish protection measures, would reduce Project-related impacts to these species.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			long-term and permanent, moderate impacts to the bent-flowered milkvetch. Therefore, the 2021 MMP may indirectly impact bent-flowered milkvetch individuals (one out of a total of approximately 653 individuals within 10 populations identified on the PNF) and habitat but would not likely contribute to a loss of viability of the species within the planning area (i.e., PNF-administered lands).(SDEIS 4-292).		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	284	Again the SDEIS appears to state that mining activities may affect one individual plant instead of disclosing that the entire subpopulation in that location may be extirpated. The assessment of impacts from dust on bent-flowered milkvetch appears to be focused on how layers of dust can negatively affect photosynthesis. The SDEIS overlooks the fact that this dust will likely contain toxic levels of arsenic that could have direct impacts on the physiology of the plants, its pollinators, and seed dispersers.	VEG	No text revisions made. Dust and the potential for arsenic are discussed in Section 4.3.2.2 and potential impacts to plants as a result of increased dust is discussed in Section 4.10.2.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	285	The SDEIS states that there may be localized, long-term and permanent, moderate impacts to this species, but the term localized is undefined. The distribution of the Cinnabar Peak population is patchy so the localized effects may not impact plants in certain areas but could impact a large number of plants in other areas. The Forest Service should clarify the term "localized" and discuss the actual effect in more detail.	VEG	Text has been added per the comment in Section 4.10.2. The term "localized" is defined at the beginning of Chapter 4 in Table 4.1-1.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	286	Under the Payette Forest Plan, bent-flowered milkvetch is a designated Forest Watch species, which calls for conducting additional baseline surveys, maintaining existing habitat, and prioritizing opportunities for mitigating effects and not accepting extirpation: Objective BTOB01: Continue to map locations of suitable occupied habitat for Region 4 Sensitive plant species, Forest Watch plants, and globally rare plant communities. Incorporate information into a GIS database and coordinate with the Idaho Conservation Data Center. Goal BTGO03 Maintain or restore globally rare plants identified as the Natural Heritage Program G1, G2, and G3 and/or S1 and S2 species, and provide for their continued compositional and functional integrity for those species for which we have habitat (see Appendix C). Objective MIOB08 During fine-scale analyses in areas where mine facilities are identified as a potential concern or problem contributing to degradation of water quality, aquatic species or occupied sensitive or Watch plant habitat, evaluate and document where the contributing mine facilities are and prioritize opportunities to mitigate effects. Following these measures does not necessarily interfere with mining activities but does require additional surveys, the adoption of additional safeguards regarding dust monitoring and management, and the development of species-specific design features to protect this subpopulation and its pollinators from additional disturbance. such as the creation of a Plant Conservation Area.	VEG	No text revisions made. Details regarding potential impacts to sensitive and watch species is provided in Section 4.10.2 and measures proposed by Perpetua and required by the Forest Service, primarily the requirement of preconstruction surveys to identify occurrences of sensitive and watch species and then establish protection measures, would reduce Project-related impacts to these species.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	287	c. Least moonwort (Payette National Forest and Region 4 Sensitive Species and Forest Watch Species) Least moonwort is a Payette National Forest and Region 4 sensitive species. Two subpopulations were observed near Johnson Creek Road in 2004. The most recent survey for them was conducted in 2005 and failed to detect any. No subsequent surveys have been done for least moonwort related to the Stibnite Gold Project or other projects in the intervening 17 years, in contradiction of the following Forest Plan objectives, standards and goals: Objective BTOB01: Continue to map locations of suitable occupied habitat for Region 4 Sensitive plant species, Forest Watch plants, and globally rare plant communities. Incorporate information into a GIS database and coordinate with the Idaho Conservation Data Center. Objective BTOB02: During fine-scale analyses in areas containing sensitive species habitat, identify and prioritize opportunities for restoring degraded Sensitive species habitat. Standard BTST01 Management actions that occur within occupied sensitive plant species habitat must incorporate measures to ensure habitat is maintained where it is within desired conditions, or restored where degraded. Goal BTGO03 Maintain or restore globally rare plants identified as the Natural Heritage Program G1, G2, and G3 and/or S1 and S2 species, and provide for their continued compositional and functional integrity for those species for which we have habitat (see Appendix C).	VEG	No text revisions made. Occurrence data for sensitive and watch species has been provided and are still accurate for the analysis. Additionally, details regarding potential impacts to sensitive and watch species is provided in Section 4.10.2 and measures proposed by Perpetua and required by the Forest Service, primarily the requirement of preconstruction surveys to identify occurrences of sensitive and watch species and then establish protection measures, would reduce Project-related impacts to these species.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			The Forest Service needs to conduct new surveys for this species to establish a proper baseline and to inform the NEPA process.		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	288	d. Blandow's helodium (Boise and Payette Forest Watch Species) Construction of the Burntlog Route could impact the hydrology of the wetland that supports a nearby occurrence of Blandow's helodium, a Forest Watch species. Dust from construction and transportation activities could also negatively affect or extirpate this population. It is unclear if there are other occurrences of this species on the Boise National Forest and within the planning area. The SDEIS appears willing to accept the loss of this population instead of providing for continued compositional and functional integrity for this S2 species, as per the Forest Plan: Goal BTGO03 Maintain or restore globally rare plants identified as the Natural Heritage Program G1, G2, and G3 and/or S1 and S2 species, and provide for their continued compositional and functional integrity for those species for which we have habitat (see Appendix C).	VEG	No text revisions made. Occurrence data for sensitive and watch species has been provided and are still accurate for the analysis. Additionally, details regarding potential impacts to sensitive and watch species is provided in Section 4.10.2 and measures proposed by Perpetua and required by the Forest Service, primarily the requirement of preconstruction surveys to identify occurrences of sensitive and watch species and then establish protection measures, would reduce Project-related impacts to these species.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	290	e. Sweetgrass, Boise National Forest Forest Watch Species Burntlog Route construction also threatens two subpopulations of sweetgrass, a Forest Watch species, near Trapper Creek by altering the hydrology of the wetland that supports this species. It is unclear if there are other occurrences of this species on the Boise National Forest and within the planning area. The SDEIS appears willing to accept the loss of this population instead of providing for continued compositional and functional integrity for this S1 species, as per the Forest Plan: Goal BTGO03 Maintain or restore globally rare plants identified as the Natural Heritage Program G1, G2, and G3 and/or S1 and S2 species, and provide for their continued compositional and functional integrity for those species for which we have habitat (see Appendix C). As mentioned above, we recommend that the Forest Service integrate additional design features to minimize disruption of the hydrology of wetlands along the Burntlog Route if it is constructed. This may include using additional and/or larger culverts and adjusting the location of the route.	VEG	No text revisions made. Occurrence data for sensitive and watch species has been provided and are still accurate for the analysis. Additionally, details regarding potential impacts to sensitive and watch species is provided in Section 4.10.2 and measures proposed by Perpetua and required by the Forest Service, primarily the requirement of preconstruction surveys to identify occurrences of sensitive and watch species and then establish protection measures, would reduce Project-related impacts to these species.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	291	f. Rannoch-rush (Forest Watch Species) This occurrence is located within 300 feet of an existing section of the Burnt Log Road. The main issues here are impacts of dust from road widening and transportation. Again, the SDEIS appears willing to accept the loss of this population instead of providing for continued compositional and functional integrity for this S2 species, as per the Forest Plan: Goal BTGO03 Maintain or restore globally rare plants identified as the Natural Heritage Program G1, G2, and G3 and/or S1 and S2 species, and provide for their continued compositional and functional integrity for those species for which we have habitat (see Appendix C).	VEG	No text revisions made. Occurrence data for sensitive and watch species has been provided and are still accurate for the analysis. Additionally, details regarding potential impacts to sensitive and watch species is provided in Section 4.10.2 and measures proposed by Perpetua and required by the Forest Service, primarily the requirement of preconstruction surveys to identify occurrences of sensitive and watch species and then establish protection measures, would reduce Project-related impacts to these species.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	294	There are a number of unaddressed threats for other subpopulations of Forest Watch and Sensitive species in other locations on the Boise and Payette National Forests. These threats include nearby noxious weeds or unauthorized recreational trails among others. The Forest Service and Perpetua Resources could undertake additional surveys so that the Forest Plan requirements are being met and take additional measures to address these threats. As a result, there could be a net increase in the number of individuals and the resilience of these other subpopulations.	VEG	No text revisions made. The Forest Service has indicated that a cutoff date for data for this EIS is 2017. However, additional preconstruction surveys for sensitive and watch plant species would be conducted in suitable habitat prior to ground-disturbing activities.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	295	2. Whitebark pine, Listed as Threatened under the ESA Whitebark pine is a critical subalpine species found in the analysis area along the proposed transmission line between Johnson Creek road and the mine site, and along the proposed Burntlog Road. Whitebark pine is also found along additional roads in the general project area, including the Riordan Lake and Meadow Creek Lookout roads, the old Thunder Mountain road, and Warm Lake Road. On December 14, 2022, the US Fish and Wildlife Service announced its decision to list whitebark pine as a threatened species under the Endangered Species Act. This rule is to become effective starting January 17, 2023. Threatened species are likely to become endangered within the foreseeable future throughout all or a significant portion of its range. The primary threat to this species is disease from	VEG	Text has been revised per the comment to update the status of the whitebark pine per the listing on December 15, 2022. Additionally, the analysis and required protection measures as well as mitigation measures required by the Forest Service have been added to the Final EIS, specifically in Sections 3.10, 4.10, and 5.10, as appropriate.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>white pine blister rust, with other threats including mountain pine beetle, altered wildfire patterns and climate change. USFWS determined that these threats are not related to habitat loss, and that habitat is not a limiting factor for the species, and therefore did not designate any critical habitat for the species. The USFWS can authorize forest management and other activities that benefit and conserve the species and certain activities, such as forest management and maintenance of existing rights-of-ways is allowed under the 4(d) rule.</p> <p>Due to the listing, there are now additional restrictions regarding the removal of whitebark pine:” The protections for whitebark pine also make it illegal to remove, possess, or damage the tree on federal lands.” Federal actions that may impact whitebark pine must now go through section 7 consultation: The conference process helps determine the likely effect of the proposed action and any alternatives to avoid jeopardy to a proposed species or destruction or adverse modification of proposed critical habitat.</p> <p>If the USFWS determines that project will result in incidental take, the USFWS must issue an incidental take permit with specific terms and conditions that are non-discretionary. The Forest Service must comply with the reasonable and prudent measures and agree to implement the terms and conditions in the USFWS’s incidental take statement to avoid potential liability.</p> <p>If the USFWS biological opinion finds that a jeopardy or adverse modification to habitat will occur, the Forest Service may adopt one of the reasonable and prudent alternatives for eliminating the jeopardy or adverse modification of habitat, offer a reasonable and prudent alternative not yet considered, or take additional other actions.</p> <p>The Federal Register specifically mentioned the Stibnite Gold Project with regard to the listing decision: Comment 25: The Nez Perce Tribe expressed concern that there is currently inconsistency in the regulatory measures and management for whitebark pine both across and within Federal land management agencies. The Tribe expressed concern about the continued persistence of whitebark pine without” standardized and adequate protection and conservation measures.” They specifically expressed concern about how the Stibnite Gold Mine Project in Idaho could affect whitebark pine if the species lacks Federal protection because that project has the potential to remove up to 1,027 whitebark pine trees and impact up to 258 ac (104 ha) of occupied habitat.</p> <p>https://www.federalregister.gov/d/2022-27087/p-156</p> <p>The USFWS provided the following response:</p> <p>As a result of these provisions in the Act, if a Federal action may affect a listed species or its critical habitat, the responsible Federal agency (action agency) must initiate consultation with the Service. Thus, because we are listing whitebark pine as a threatened species under the Act, before Federal agencies can authorize development projects on Federal land, action agencies will need to consider whether these projects may affect whitebark pine (in addition to any other listed species in the action area). If the activities may affect any listed species, the Federal agency must initiate consultation with the Service. Therefore, section 7 consultation processes will ensure that development and extractive activities on Federal lands do not jeopardize the continued existence of whitebark pine, or any other listed species. We have not yet received a biological assessment for the Stibnite Gold Mine project, a proposed mining operation on Federal public land (namely USFS land) and private land in Idaho, and thus section 7 consultation has not yet occurred for the project; when it does occur, this consultation process will consider effects to whitebark pine, and any other listed species, as described above.</p> <p>https://www.federalregister.gov/d/2022-27087/p-157</p> <p>Consultation regarding the maintenance of existing transmission lines is covered under the 4(d) rule and may be relatively straightforward, but we maintain that new transmission lines or expansion of transmission lines as proposed in the Stibnite Gold Project, will require additional consultation: We recognize that relevant Federal agencies have already completed section 7 consultations to analyze the effects of construction and maintenance of utility lines in Federal rights-of-way on currently listed species. However, if these existing consultations do not consider the effects of these actions on whitebark pine, Federal agencies will need to reinitiate consultation on these ongoing vegetation-</p>		

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>management activities if they may affect whitebark pine. Federal agencies are obligated to ensure that the activities that they authorize, such as maintenance of a utility line, do not jeopardize listed species, so they must reinitiate consultation if these existing consultations do not adequately examine whether these activities could jeopardize whitebark pine. However, as we discuss in our responses to Comment 18 and Comment 50, above, these vegetation-management activities are excepted in the 4(d) rule because they do not present a threat to whitebark pine at the species level and may reduce the risk of high-severity fire, which would benefit the species. Thus, given that we find these types of activities would not present a species-level threat and may be beneficial, reinitiated consultation on the basis that these activities may affect the newly listed whitebark pine would likely be straightforward.</p> <p>https://www.federalregister.gov/d/2022-27087/p-234</p> <p>The Forest Service has preliminarily determined that neither the Johnson Creek Route Alternative nor the Burntlog Route Alternative would impact whitebark pine individuals but would not jeopardize the continued existence of this species. However, consultation will still be required: However, while the 4(d) rule excepts forest-management activities because they do not present a species-level threat, section 7 concurrence or consultation will still be required if a forest-management activity with a Federal nexus may affect whitebark pine, even if this activity would only affect individual trees or populations. (Emphasis added).</p> <p>https://www.federalregister.gov/d/2022-27087/p-237</p> <p>We added vegetation management of existing utility rights-of-way as an example of forest-management activities covered under the 4(d) rule in Provisions of the Final 4(d) Rule, below. Importantly, construction of new utility lines on Federal lands is not an excepted activity under the 4(d) rule (i.e., it is not forest management); if that construction could result in prohibited removal or damage of whitebark pine, Federal agencies and associated utility companies would need to pursue appropriate permitting and consultation processes. (Emphasis added.)</p> <p>https://www.federalregister.gov/d/2022-27087/p-232</p> <p>According to the SDEIS, the analysis area contains approximately 2,069 acres occupied by whitebark pine. Even though the Forest Service has preliminarily determined that neither alternative would jeopardize the species, the SDEIS notes that activities related to the Stibnite Gold Project would negatively affect both whitebark pine habitat and individuals: The SGP would remove whitebark pine individuals, and habitat conversion associated with the SGP would impact seed production, dispersal, and establishment of this species. SDEIS 2-144.</p> <p>The Vegetation Communities, Botanical Resources, and Non-Native Plants Specialist Report highlights the potential impacts to known locations of whitebark pine” .</p> <p>7.2.1.6 Issue: Impacts to Known Locations of Whitebark Pine</p> <p>Construction would require removal of known whitebark pine individuals. Direct impacts to whitebark pine individuals would occur during the construction and operation phases. Removal of whitebark pine individuals, particularly mature, cone-bearing individuals, would reduce the population size of this species in the Forests and potentially have long-term consequences for this species in the analysis area. Loss of whitebark pine individuals would result in reductions in seed production and dispersal, which would result in reduced establishment of this species in and adjacent to the analysis area.</p> <p>Transport of whitebark pine individuals that are cut down for SGP construction outside the SGP area also has the potential to spread bark beetle species (e.g., mountain pine beetle [Dendroctonus ponderosae]), which are a main cause of tree mortality in the coniferous forests of the western U.S. in recent years (Hinke et al. 2016). White pine blister rust disease, which is caused by the introduced pathogen Cronartium ribicola, is a conifer pathogen (Keane et al. 2017) that has the potential to spread if infected trees are transported outside the SGP area. This pathogen and bark beetles are a threat to</p>		

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>whitebark pine in the PNF and BNF, and their potential spread as a result of SGP actions could detrimentally impact whitebark pine and other conifers within and outside the analysis area.</p> <p>The botanical surveys are intended to cover both direct impacts and indirect impacts up to 300 feet to factor in effects to pollinators and from dust. However, we are concerned that even this broader analysis misses several potential impacts from dust suppressant, soil contamination, recreationalists, and climate change, among other impacts.</p>		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	296	<p>a. The SDEIS failed to analyze the potential impacts of soil contamination on whitebark pine.</p> <p>In addition to interfering with photosynthesis, dust contaminated with heavy metals can affect soils and harm plant physiology. We are concerned that the SDEIS fails to consider impacts to whitebark pine and other botanical resources within and adjacent to the Operations Area Boundary from air quality/pollution and mercury or other heavy metal contamination stemming from onsite ore processing.</p> <p>We are also concerned about the physical and chemical effects of fugitive dust to botanical resources along the transportation route. IDEQ itself states on page 22 of the final SOB that "it may prove challenging to consistently and continuously achieve the targeted level of fugitive dust control for emissions from traffic on unpaved roadways, with over 55 miles of haul truck routes within the mining operations boundary, a fleet of 32 haul trucks weighing between 37 and 357 tons, and a targeted dust control efficiency of 93.3% accomplished by application of both dust suppressant and water controls." The Forest Service needs to take a closer look at these potential impacts.</p>	VEG	Text has been revised per the comment to update the status of the whitebark pine per the listing on December 15, 2022. Additionally, the analysis and required protection measures as well as mitigation measures required by the Forest Service have been added to the Final EIS, specifically in Sections 3.10, 4.10, and 5.10, as appropriate.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	297	<p>b. The SDEIS failed to analyze the impacts of dust suppressants on whitebark pine.</p> <p>As noted above, dust control measures are critically important but they have to be applied carefully to avoid unintended effects. Magnesium chloride is a now commonly used liquid chemical mix applied to unpaved roads as a dust suppressant and to both paved and unpaved roads as a deicing agent. Numerous studies demonstrate that the use of magnesium chloride on road surfaces results in adverse conditions affecting the health of roadside vegetation, including aspen, Engelmann spruce, and lodgepole and ponderosa pine. Each of these studies found that exposure to commercial deicers and dust suppressing agents using magnesium chloride as a base adversely affects these four tree's life cycles, reducing or inhibiting foliage growth, depressing leaf photosynthesis rates, and increasing sapling mortality.</p> <p>The adverse impacts associated with the use of magnesium chloride are not restricted to vegetation immediately adjacent to the roadside. Researchers have documented foliage loss and mortality and high sodium concentrations up to 93 meters downslope of the application area. While none of the cited studies document whitebark pine impacts, it is worth noting that few, if any, studies on the effects of magnesium chloride incorporate alpine or subalpine environs. Considering the adverse effects magnesium chloride has on Engelmann spruce, as well as lodgepole and ponderosa pine, it is not unreasonable to project potential impacts to whitebark pine and other species if magnesium chloride solutions are used for dust suppression or as a de-icing agent. The Forest Service needs to determine if magnesium chloride will play a role in dust abatement and winter road maintenance, and if so, fully analyze and disclose the potential impacts to whitebark pine in the analysis area. We recommend that the Forest Service provide the results of this analysis in a supplemental SDEIS.</p>	VEG	Text has been revised per the comment to update the status of the whitebark pine per the listing on December 15, 2022. Additionally, the analysis and required protection measures as well as mitigation measures required by the Forest Service have been added to the Final EIS, specifically in Sections 3.10, 4.10, and 5.10, as appropriate.
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	298	<p>c. The SDEIS fails to consider long-term impacts of climate change.</p> <p>Known effects of climate change include rising temperatures, decreased snowpack, and increased rain-associated precipitation. These factors could affect the resilience of whitebark pine over the next two decades, and the SDEIS fails to consider the potential impacts to the long-term success of whitebark pine should the analysis area population suffer additional losses. As recounted elsewhere in these comments, we recommend the Forest Service analyze the findings of climate change cumulative impacts in a supplemental SDEIS.</p> <p>d. The SDEIS fails to consider the effects of motorized public recreational use of the Burntlog Route on whitebark pine.</p>	VEG	Text has been revised per the comment to update the status of the whitebark pine per the listing on December 15, 2022. Additionally, the analysis and required protection measures as well as mitigation measures required by the Forest Service have been added to the Final EIS, specifically in Sections 3.10, 4.10, and 5.10, as appropriate.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>Motorized access through whitebark pine habitat will be greatly expanded if public use of the Burntlog Route is allowed. While recreational activity is not a threat to whitebark pine populations, additional recreational activities in this subalpine area could affect individual whitebark pine and increase the cumulative effects of the predicted impacts. Members of the public who do not follow the Motor Vehicle Use Map can drive vehicles off designated routes and run over whitebark pine seedlings. Campers may also cut down whitebark pine for firewood or to enlarge campsites and parking areas at dispersed camping areas. The SDEIS also notes the possibility of motorized wilderness incursions into the FCRNRW, which would further increase the potential impacts on whitebark pine. In addition, the majority of fires in Idaho are human-caused. While certain fires can be beneficial to whitebark pine by reducing surface fuel loads and competition, uncharacteristic wildfires can be detrimental, as highlighted in the SSA:</p> <p>Although some experts have suggested that whitebark pine is phenotypically adapted to survive low-intensity fire, Stevens et al. (2020, p.948) found that whitebark pine had relatively thin bark compared to other conifer species and, based on a systematic ranking of numerous traits associated with fire resistance in western conifers, whitebark pine was found to have one of the lowest fire resistance scores of the 29 conifers examined in the study. Others have also observed that whitebark pine trees can be sensitive to bole (main stem of the tree) scorching, resulting in cambium injury or death, even from low-intensity fire (Hood et al. 2008, p. 66). Keane et al. (2020, p. 7) noted several recent reports of prescribed fire and low-intensity fire killing whitebark pine trees, despite pre-fire site preparation activities implemented to reduce or modify surface and ladder fuels and protect the residual whitebark pine trees. Keane and Parsons (2010, p. 63) studied the effects of seven different fuel treatment combinations on whitebark pine at five treatment sites in Montana and Idaho and found that whitebark pine mortality from low-intensity fire was comparable to subalpine fir under all treatment combinations. As a result, empirical evidence shows that low-intensity fire in whitebark pine can result in higher-severity fire effects.</p> <p>And</p> <p>Despite adaptations that allow whitebark pine to recolonize areas that experience high-severity fire effects, the ability of whitebark pine to regenerate and reestablish following high-severity fire has been disrupted by white pine blister rust in many areas. This novel stressor makes the species more vulnerable to the impacts of fire (see Chapter 4: Analysis of Current Conditions). Blister rust has killed many mature whitebark pine trees, effectively reducing or eliminating whitebark pine seed sources. The presence of blister rust also reduces whitebark pine seedling survival, which significantly reduces the species' ability to regenerate in fire-created openings that are typically ideal for seedling establishment.</p> <p>Wildfires are also expected to become more severe due to climate change and mountain pine beetle activity. Human-caused wildfires in areas made accessible to the general public by the Burntlog Route are reasonably foreseeable. These impacts would be from activities completely unrelated to mining activities and would be largely preventable if the Forest Service decides to not allow public motorized access along the Burntlog Route or selects the Johnson Creek alternative.</p>		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	299	<p>e. Indicators used to assess impacts to whitebark pine are incomplete.</p> <p>The SDEIS uses two indicators to estimate impacts on whitebark pine. The first indicator is the SDEIS used to estimate impacts on whitebark pine is the acres of habitat affected:</p> <p>The 2021 MMP would remove an estimated 259.4 acres of occupied whitebark pine habitat (12.5% of occupied habitat in the analysis area).</p> <p>The Johnson Creek Route Alternative would remove an estimated 108.4 acres of occupied whitebark pine habitat (5.2% of occupied habitat in the analysis area). SDEIS 2-144.</p> <p>The second indicator of impacts to whitebark pine is the estimated number of mature whitebark pine trees to be cut during construction activities. The SDEIS also includes an estimate on the number of</p>	VEG	Text has been revised per the comment to update the status of the whitebark pine per the listing on December 15, 2022. Additionally, the analysis and required protection measures as well as mitigation measures required by the Forest Service have been added to the Final EIS, specifically in Sections 3.10, 4.10, and 5.10, as appropriate.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>individual trees which will be cut, which is critically important for distinguishing between alternatives and should be ranked as a third indicator:</p> <p>An estimated 1,236 individual trees, 23 of which would be cone-bearing trees, would be removed under the 2021 MMP. SDEIS 2-144.</p> <p>An estimated 767 individual trees, 23 of which would be mature, cone-bearing trees, would be removed under the Johnson Creek Route Alternative. SDEIS 2-144</p> <p>Consideration of mature trees is important and appropriate as it may take 40-80 years for a whitebark pine to reach reproductive age:</p> <p>Mature tree life stage: Some whitebark pine individuals are capable of producing limited amounts of seed cones at 20– 30 years of age, although large cone crops usually are not produced until 60–80 years (Krugman and Jenkinson 1974, as cited in McCaughey and Tomback 2001, p. 109), with average earliest first cone production at 40 years (Tomback and Pansing 2018, p. 7). Therefore, the generation time of whitebark pine is approximately 40 to 60 years (Tomback and Pansing 2018, p. 7; COSEWIC 2010, p. v). Mature whitebark pine trees require two summers of suitable temperatures and precipitation for fertilized cones to mature (Rapp et al. 2013, p. 2).</p> <p>The impacts to the total number of whitebark pine should be included as an equally important third indicator. There are many more younger whitebark pine trees that may be removed by mining activities. While they may not have reached reproductive age yet, these smaller and younger trees are more resistant to mountain pine beetles than mature trees and are important to retain as well.</p>		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	300	<p>f. Baseline surveys on whitebark pine are insufficient.</p> <p>We have concerns about the methodologies used to complete some baseline surveys. Regarding the acreage of occupied habitat, Forest Service is appropriately basing this information on modeled suitable habitat and field surveys for whitebark pine. Field surveys were conducted on 89% of the areas that are modeled as suitable habitat and that are associated with the disturbance footprint of the mine and associated roads, transmission line corridors and OSV routes. Surveys found whitebark pine occupying 42% of the surveyed area:</p> <p>Surveys in 2012, 2013, 2014, and 2019 documented whitebark pine at the proposed mine site and along Burntlog Road and several existing roads, including Riordan Lake Road and Meadow Creek Lookout Road, and along the existing Old Thunder Mountain Road, and within the proposed power line corridor, especially between Johnson Creek Road and the mine site (HDR 2013, 2014, 2017; Tetra Tech 2019). Stibnite Gold Project, Vegetation Communities, Botanical Resources, and Non-Native Plants Specialist Report, D-10.</p> <p>We are concerned that surveys for whitebark pine did not go into sufficient detail to establish the needed baseline information or to provide the public with sufficient information to make meaningful comments. The Forest Service does not have an accurate count of the live and cone-producing trees in a polygon. Instead, the numbers the SDEIS used for mature trees and total trees removed are estimated based on a formula with various inputs. This formula takes the acres directly impacted by proposed mining activities, divides them by the total acres in the polygon and multiplies this by the approximate live trees in the polygon. The problem with this approach is that for some polygons, there was an incredibly wide range of trees, ranging from 150-500 or 500-1000 or 1000+. The Forest Service just selected a "midpoint" number in that range and plugged it into the formula which may be prone to over or underestimations of whitebark pine.</p> <p>As shown in Table F-1, the Forest Service estimated the number of whitebark pine trees in occupied habitat polygons #15, 71, 84 and 85 ranged anywhere between 150 to 500 individuals and came up with a midpoint amount that was entered into the formula. The Forest Service then estimated that 67, 11, 35 and 33 trees would be removed respectively from each polygon. However, if the input ranges from 150-500 individuals, this could lead to a 300% or greater discrepancy in the results. No sorts of error bars or</p>	VEG	Text has been revised per the comment to update the status of the whitebark pine per the listing on December 15, 2022. Additionally, the analysis and required protection measures as well as mitigation measures required by the Forest Service have been added to the Final EIS, specifically in Sections 3.10, 4.10, and 5.10, as appropriate.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>degree of certainty accompanies the estimate of trees to be removed, which makes it difficult for the public and decision makers to understand the potential impacts.</p> <p>While some passages in the SDEIS clarify that the number of individual whitebark pine trees that could be affected are estimates, other passages do not:</p> <p>The 2021 MMP would remove an estimated 259 acres of occupied whitebark pine habitat (12.5% of occupied habitat in the analysis area), totaling 1,236 trees (23 would be mature, cone-bearing). SDEIS ES-16. Emphasis added.</p> <p>The level of specificity used implies that this is an exact count with a high degree of accuracy instead of the output of a formula that may be off by several hundred percent in some polygons.</p> <p>Another example is occupied habitat polygon #105 which appears to be in the proposed footprint of the West End pit. The Forest Service estimated that this polygon has anywhere between 500-1000 trees, out of which the Forest Service used the formula based on a midpoint to estimate that there were 17 mature whitebark pine trees that would be removed. The margin for error for this important calculation is undisclosed and unacceptable.</p> <p>With this margin of error, it is difficult to make an informed decision about the impacts of Stibnite Gold Project, real differences regarding the Burntlog Route and the Johnson Creek Route Alternatives and how to develop design features to avoid, minimize and mitigate impacts. This is a significant problem regarding a listed species. We note that the lack of a sufficient baseline study for Sacajawea's bitterroot for the CuMo Mine Exploration Project was sufficient for the court to remand the decision.</p> <p>While the formula used may be appropriate for coarse surveys for relative abundance of whitebark pine and in areas with numerous seedlings and saplings, the Forest Service should follow up with additional field surveys for accurate counts of mature trees where they occur. This should not be an undue burden as the area directly affected by mine operations in polygon #105 is less than 5 acres and is warranted as whitebark pine is a listed species.</p> <p>While we appreciate the Forest Service posting the whitebark pine survey on the web page, it was not posted until Dec. 29, 2022. The survey report contained graphics showing the estimated range of the number of whitebark pine in the different polygons as well as the area of disturbance of the mine. However, the area of disturbance depicted is based on the 2019 Mine Plan, which differs from the 2021 MMP. As such, it is very difficult for the public to ascertain if a whitebark pine polygon really is going to be consumed in a mine pit or not. For example, polygons 105, 106 and 112 contain mature whitebark pine which would appear to be consumed by the West End pit (see Map 1 in the Whitebark Pine Survey). However, the West End pit boundary in the 2021 MMP appears to have a different location and shape (see Figure 2.4-2 in the SDEIS). The Whitebark Pine Survey needs to be updated so the actual proposed layer of disturbance appears along with the verified mature trees in the polygons and then made available for public comment in a Supplemental SDEIS.</p>		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	301	<p>g. Avalanche control on whitebark pine not properly assessed.</p> <p>As mentioned previously, avalanche control work has the potential to artificially trigger avalanches that would not otherwise have occurred and therefore destroy or damage whitebark pine. It is not clear that whitebark pine surveys conducted by Perpetua included individuals living within avalanche starting zones, tracks, or runouts. The SDEIS should ensure that all species members impacted by SGP activities are accounted for in these surveys. Artificially triggering avalanches, while beneficial for decreasing risk that vehicles will be struck, may also incidentally take whitebark pine individuals. This impact should also be addressed.</p>	VEG	Text has been revised per the comment to update the status of the whitebark pine per the listing on December 15, 2022. Additionally, the analysis and required protection measures as well as mitigation measures required by the Forest Service have been added to the Final EIS, specifically in Sections 3.10, 4.10, and 5.10, as appropriate.
Bonnie Gestring (Northwest Program Director,	17634	302	<p>h. The 2021 MMP/Burntlog Route appears to have significantly greater impacts on whitebark pine than the Johnson Creek alternative.</p> <p>Based on the incomplete information provided so far, the Burntlog Route appears to be the worst alternative for whitebark pine for both direct and cumulative effects:</p>	VEG	Text has been revised per the comment to update the status of the whitebark pine per the listing on December 15, 2022. Additionally, the analysis and required protection measures as well as mitigation measures required by the Forest Service have been added to the Final EIS, specifically in Sections 3.10, 4.10, and 5.10, as appropriate.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
Earthworks) and seven others			<p>The preferred alternative would remove approximately 12.5% of occupied whitebark pine habitat in the project's analysis area covering 259.4 acres and remove a (greatly) estimated 1,236 trees, 24 of which would be cone-bearing trees. The Johnson Creek alternative would remove whitebark pine from 5.2% of occupied habitat in the same area covering 108.4 acres and remove a (greatly) estimated 767 trees, 23 of which would be cone-bearing trees.</p> <p>For whitebark pine, the potential for cumulative impacts would be lowest under the Johnson Creek Route Alternative and highest under the 2021 MMP based on disturbance acreage and estimated number of trees removed. The Stibnite Gold Project, Vegetation Communities, Botanical Resources, and Non-Native Plants Specialist Report, p. 82.</p> <p>These impacts would be irretrievable:</p> <p>7.6.2.2 Irretrievable Whitebark pine individuals removed for construction of the SGP would be irretrievable. Vegetation impacts also would be greater under the 2021 MMP in the area of the Meadow Creek Lookout Road (Forest Road 51290) from the Burntlog Route at the upper portion of Blowout Creek drainage to Monumental Summit, which would be improved for public access to connect with Thunder Mountain Road under this alternative.</p> <p>The Burntlog Route could also spread pathogens to the greater density of whitebark pine along this corridor and to the Chilcoot Peak RNA, where whitebark pine are one of the distinguishing features of the RNA.</p> <p>Timber harvested at the SGP could be transported on Burntlog Route. Timber from the SGP could have conifer pathogens such as pathogenic bark beetle species (e.g., mountain pine beetle [<i>Dendroctonus ponderosae</i>]), and white pine blister rust, which is caused by the introduced pathogen <i>Cronartium ribicola</i> (Hinke et al. 2016; Keane et al. 2017)...Conifer pathogens could be distributed during the transport of timber on the Burntlog Route... Whitebark pine/subalpine fir habitat type is one of the distinguishing features of the Chilcoot Peak RNA, and conifer pathogens could cause mortality of whitebark pine and other conifers. If this occurs, changes in the composition and structure of existing vegetation communities and ecological succession would result in a localized, minor to major, long-term loss of the Chilcoot Peak RNA research value and ecological condition. Stibnite Gold Special Designations Specialist Report p. 89.</p>		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	303	<p>i. The Environmental Design Features for whitebark pine proposed thus far are inadequate:</p> <p>The Environmental Design Features include a requirement for flagging trees in advance of construction: Prior to construction disturbance, all known populations and/or individuals of whitebark pine within 300 feet of the SGP area would be flagged by the qualified environmental professional (QEP). Any anticipated impacts would be reported to the Forest Service.</p> <p>Instead of having the proponent identify all known populations of whitebark pine and reporting anticipated impacts to the Forest Service prior to construction, the Forest Service needs to conduct proper baseline surveys and disclose the anticipated effects as part of the NEPA process in a Supplemental SDEIS.</p> <p>The whitebark pine survey shows several locations where a slight realignment of the road or transmission corridor would appear to avoid impacting a large number of whitebark pine trees. For example, polygon number 97 in map 11 shows the new proposed mine road branching off to the northeast from the Meadow Creek lookout road and down to the mine site. This intersection contains 1,000+ whitebark pine, which highlights the problems of the Burntlog Route. Just a few hundred feet north of this intersection, there are no identified whitebark pine within the surveyed polygon. At one point, Midas Gold/Perpetua had considered an alternate route going due north of this intersection which is marked as suitable but unsurveyed habitat. If the Burntlog Route is selected, one way to reduce impacts on whitebark pine is to move the intersection slightly to the north to use the first part of the original proposed route.</p>	VEG	Text has been revised per the comment to update the status of the whitebark pine per the listing on December 15, 2022. Additionally, the analysis and required protection measures as well as mitigation measures required by the Forest Service have been added to the Final EIS, specifically in Sections 3.10, 4.10, and 5.10, as appropriate.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>Similarly, polygon number 18 in map 3 shows that whitebark pine occurs in the northern half of the proposed transmission line corridor and not in the southern half. A slight adjustment to the south of this corridor could reduce impacts.</p> <p>While most of the whitebark pines were in the seedling and sapling stages, the Whitebark Pine Survey made note of particular polygons where live mature trees were seen. We recommend prioritizing the mature trees in these polygons for retention and adjusting the footprint of disturbance accordingly:</p> <p>Many large snags were observed, but fewer live mature trees were seen. Some notable exceptions are polygon 87 (Appendix A, Map 13) near Meadow Creek Lookout, polygon 84 (Appendix A, Map 14, Figure 3-5) along Meadow Ridge, and in polygon 106 (Appendix A, Map 1) in the upper north facing reaches of West End Creek. These ridgetop locations have mature live trees, and large old snags...Additional polygons where mature whitebark pines were noted included polygon 34 (Appendix A, Map 25), polygon 54 (Appendix A, Map 18), polygon 66 Appendix A, Maps 18-19), polygon 96 (Appendix A, Map 10), polygon 98 (Appendix A, Map 10), polygon 105 (Appendix A, Map 1), polygon 107 (Appendix A, Map 1).</p> <p>It appears that both alternatives propose removing an estimated 23-24 mature, cone-bearing whitebark pine trees because this location would be consumed by the West End pit. This polygon contains a relatively large amount of mature trees with less than 5% blister rust of pine beetle markings. The mine footprint would completely eliminate the western third of this 3.63 acre polygon. We recommend investigating whether an engineering adjustment of the West End pit could be made that avoids or reduces the impacts on this stand of whitebark pine. One would hope that the engineering design for this pit contains an extra margin of safety and perhaps this does not require extending the pit wall as far to the east. Another option might be to see if a small peninsula could be retained that supports these mature trees and can be offset by a modified bench beneath it.</p>		
Samuel Penney (Chairman)	19396	113	<p>The SDEIS discloses that the analysis area for vegetation covers over 17,000 acres across three national forests and private land. The analysis includes impacts to vegetation, including 11 forested potential vegetation types (“PVG”) (dominated by Persistent Lodgepole Pine (<i>Pinus contorta</i>; qalámqalam) and Warm, Dry Subalpine Fir (<i>Abies lasiocarpa</i>; patóysiwey) PVGs, followed by water, rock, and barren non-forest which cover 18% of the analysis area), botanical resources (i.e., special status plant species), and non-native plants (i.e., invasive and noxious plant species).</p> <p>Existing disturbance is approximately 1,126 acres on NFS lands. Approximately 3,046 acres of land in the analysis area occurs on lands not administered by the Forest. Chapter 3.10 should cross-reference to sections which describe vegetation in the affected environment for Heritage Resources (Chapter 3.17) and Tribal Rights and Interests (Chapter 3.24). Many of the plant resources used by the Tribe are briefly described in the SDEIS,216 but it would help if these plant resources were discussed in reference to vegetation classifications (i.e., existing vegetation communities in the PVGs, non-forested types, and LANDFIRE mapping) found within the Project area.</p>	VEG	Text has been added per the comment. Additional information has been added to Section 3.17 and Section 3.24 of the Final EIS regarding these plant species and Section 3.10 and 4.10 is cross-referenced within Section 3.17 and 3.24.
Samuel Penney (Chairman)	19396	114	<p>Surface soils in the analysis area contain metals, specifically antimony, arsenic, mercury, and silver, from legacy mine operations. Arsenic levels at the Project area are particularly high and have the greatest potential to cause phytotoxicity in plants. The SDEIS needs to disclose information regarding existing conditions of these metals in the vegetation growing at the site. The SDEIS states that “[s]oils near the SGP that exceed the screening-level phytotoxicity criteria do continue to sustain native vegetation.” However, the SDEIS fails to detail the type, extent, and quality of this “native vegetation” and whether there are toxic levels of metals detected in this vegetation. This information needs to be included in the SDEIS (i.e., as part of the affected environment for vegetation).</p>	VEG	No text revisions made in the vegetation section of the EIS as this information is already located in the soils section. Information regarding metals in the soils in the Project area are discussed in detail in Section 3.5.
Samuel Penney (Chairman)	19396	115	<p>Special Status Plant Species</p> <p>The SDEIS covers one ESA-threatened species (whitebark pine (<i>Pinus albicaulis</i>; lálxsaway)), two Forest Sensitive species (least moonwort (or little grapefern219) (<i>Botrychium simplex</i>) and Sacajawea’s bitterroot (<i>Lewisia sacajaweanana</i>)), four Forest Watch species (bent-flower milkvetch (<i>Astragalus vexilliflexus</i> var. <i>vexilliflexus</i>), Blandow’s helodium moss (<i>Helodium blandowii</i>), sweetgrass</p>	VEG	Text has been added per the comment. Additional information has been added to Table 3.10-5.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			(<i>Hierochloa odorata</i>), and Rannoch-rush (<i>Scheuchzeria palustris</i>)), and non-native plants known to occur within or immediately adjacent to the Project area. The SDEIS also identifies modeled potential habitat for 29 Sensitive and/or Forest Watch species that occur across approximately 19,492 acres. The Tribe takes great interest in the status and recovery of these species, as many have important direct and indirect cultural significance. The SDEIS needs to add associated habitat types for the special status species, including whether the species is a wetland, riparian, or upland plant. This information could be added in Table 3.10-5. According to the most current National Wetland Plant List, seven of the 29 plant species are obligate to wetlands. The SDEIS should also consider impacts to plant species listed in an updated draft of the Idaho State Wildlife Action Plan (“SWAP”) which includes 42 plant species identified as either species of greatest conservation need (“SGCN”) or species of greatest information need (“SGIN”).		
Samuel Penney (Chairman)	19396	116	<p>Whitebark pine is listed as a threatened species under the ESA of 1973, as amended. The current and predicted range of whitebark pine occurs across the Tribe’s aboriginal homeland, much of which is now National Forest Service land (including lands and waters of Boise and Payette National Forests). Conservation and restoration of this species is of great importance to the Tribe.</p> <p>According to Mathys et al., whitebark pine is stressed at the margins of its current range with very few locations for potential expansion. Limber pine (<i>Pinus flexilis</i>), another five-needle pine, is also documented in the Project area. High-elevation five-needle white pines are important functional and structural components of high elevation landscapes. These long-lived pines stabilize soils, reduce soil erosion, shade snowpack, regulate snowmelt and downstream runoff, and provide a high-energy food source for important wildlife species, including grizzly bears (<i>Ursus arctos horribilis</i>; xáxaac), black bears (<i>U. americanus</i>; yá·ka’), and many bird and small mammal species at high elevation. Five-needle pine forests are declining across most of their range in western North America due to the combined impacts of insects, pathogens, altered fire regimes, and shifting moisture regimes associated with climate change. The loss of these species would have serious, adverse consequences for community biodiversity and stability in high-elevation ecosystems.</p> <p>Whitebark pine occurs throughout the Project area and across both Forests, while the limber pine stand may be the only documented population of this species on the Payette Forest Clark’s nutcracker (<i>Nucifraga columbiana</i>; ?ispú·kux) and red squirrel (<i>Tamiasciurus hudsonicus</i>; cílmi) are extremely important to limber and whitebark pine conservation because they collect and disperse whitebark pine seeds. The mutualistic relationship between Clark’s nutcracker and these pines is highly evolved and important for the survival and well-being of these species.</p>	VEG	Text has been revised per the comment to update the status of the whitebark pine per the listing on December 15, 2022. Additionally, the analysis and required protection measures as well as mitigation measures required by the Forest Service have been added to the Final EIS, specifically in Sections 3.10, 4.10, and 5.10, as appropriate.
Samuel Penney (Chairman)	19396	117	Whitebark pine surveys were conducted in 2012, 2013, 2014, and 2019. The most recent survey in 2019 was associated with the Forests’ DEIS Alternative 2 disturbance footprint. The analysis needs to be updated to reflect the footprint of alternatives analyzed in the SDEIS. Surveys documented over 6,000 acres of potential habitat within the Project area and over 2,000 acres of occupied whitebark pine habitat within the 300-foot buffer and overlaps actions proposed for utilities, access roads, and the mine site. Under ESA protections it is unlawful to commit, to attempt to commit, to cause to be committed, or to solicit another to commit the following acts for whitebark: removal from federal lands, malicious damage, or destruction on federal lands, engaging in interstate or foreign commerce, and import or export into, out of, or through the U.S. The Forest must fulfill relevant Section 7 consultation requirements for whitebark pine. Connected actions on private lands should also be considered in analyses of the Project, even though the Forests may not have jurisdiction over the activities occurring on private lands.	VEG	Text has been revised per the comment to update the status of the whitebark pine per the listing on December 15, 2022. Additionally, the analysis and required protection measures as well as mitigation measures required by the Forest Service have been added to the Final EIS, specifically in Sections 3.10, 4.10, and 5.10, as appropriate.
Samuel Penney (Chairman)	19396	118	<p>Least moonwort (or little grapefern) is a native, perennial, facultative hydrophyte fern. It is listed on the National Wetland Plant List as a facultative perennial fern (occurs in wetlands and nonwetlands).</p> <p>According to the SDEIS, two subpopulations of a single occurrence occur in swales adjacent to Johnson Creek Road. To realize the full impacts to these subpopulations, the Forest needs to revisit these sites and potential habitat (838 acres), assess impacts, and disclose them in the SDEIS. These sites have not been surveyed since 2005. <i>Sacajawea</i>’s bitterroot is a native perennial with succulent rosette leaves,</p>	VEG	No text revisions made. Occurrence data for sensitive and watch species has been provided and are still accurate for the analysis. Additionally, details regarding potential impacts to sensitive and watch species is provided in Section 4.10.2 and measures proposed by Perpetua and required by the Forest Service, primarily the requirement of preconstruction surveys to identify occurrences of sensitive and watch species and then establish protection measures, would reduce Project-related impacts to these species.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			white flowers, and a tuberous root. Endemic to central Idaho, a single occurrence of <i>Sacajawea's</i> bitterroot occurs approximately 300 feet above the Warm Lake Road and the existing transmission line corridor near the intersection of Warm Lake Road and Curtis Creek Road. The occurrence was last observed in 1999 and not documented in 2014 surveys (which occurred in late June). This species has a very short growing season and aboveground parts disappear quickly after flowering (May/June). To realize the full impacts to this occurrence of <i>Sacajawea's</i> bitterroot, the Forest needs to revisit the site and potential habitat (2,351 acres) during its growing season, assess impacts, and disclose them in the SDEIS.		
Samuel Penney (Chairman)	19396	119	Both Forest Plans include Guideline BTGU01 which states" [f]or site/project-scale analysis, suitable habitat should be determined for Sensitive species within or near the project area. Conduct surveys for those species with suitable habitat to determine presence. Document the rationale for not conducting surveys for other species in the project record." The Forest needs to update surveys and location information for least moonwort and <i>Sacajawea's</i> bitterroot, and for the other Sensitive plant species that have potential habitat in the Project area but have not been included in past special status surveys for the Project. These include candystick (<i>Allotropa virgata</i>) (390 acres of potential habitat), scalloped moonwort (<i>Botrychium crenulatum</i>) (74 acres of potential habitat), slender moonwort (<i>Botrychium lineare</i>) (838 acres), beautiful bryum (<i>Bryum calobryoides</i>) (28 acres), Cascade reedgrass (<i>Calamagrostis tweedyi</i>) (3,884 acres), Idaho douglasia (<i>Douglasia idahoensis</i>) (176 acres), bank monkeyflower (<i>Mimulus clivicola</i>) (404 acres), Tolmie's saxifrage (<i>Saxifraga tolmiei</i> var. <i>ledifolia</i>) (691 acres), and short-style tofieldia (<i>Triantha occidentalis</i> ssp. <i>brevistyla</i>) (532 acres).	VEG	No text revisions made. Occurrence data for sensitive and watch species has been provided and are still accurate for the analysis. Additionally, details regarding potential impacts to sensitive and watch species is provided in Section 4.10.2 and measures proposed by Perpetua and required by the Forest Service, primarily the requirement of preconstruction surveys to identify occurrences of sensitive and watch species and then establish protection measures, would reduce Project-related impacts to these species.
Samuel Penney (Chairman)	19396	120	There are four Forest Watch species documented in the Project area (bent-flower milkvetch, Blandow's helodium moss, sweetgrass, and Rannoch-rush). Bent-flower milkvetch is a perennial legume with white to purple flowers and grows low to the ground on exposed, subalpine ridgelines in subalpine fir and whitebark pine habitats. It is critically imperiled in Idaho. The nearest subpopulation occurs upslope and east of the West End Creek diversion and is the largest contiguous area of habitat and important to long-term viability of this species.	VEG	No further response required. General in nature or position statement.
Samuel Penney (Chairman)	19396	121	Blandow's helodium moss (also named <i>Elodium blandowii</i>) forms in mats and hummocks in wet areas of the forest (e.g., fens, wetlands, and near streams). One occurrence is located near Trapper Creek within 300 feet of Burntlog Route, but there are 705 acres of mapped potential habitat. Imperiled in Idaho, northern sweetgrass (also named <i>Heirochloe hirta</i>) is found in wetlands near Trapper Creek and mapped with having 996 acres of potential habitat.	VEG	No text revisions made. Occurrence data for sensitive and watch species has been provided and are still accurate for the analysis. Additionally, details regarding potential impacts to sensitive and watch species is provided in Section 4.10.2 and measures proposed by Perpetua and required by the Forest Service, primarily the requirement of preconstruction surveys to identify occurrences of sensitive and watch species and then establish protection measures, would reduce Project-related impacts to these species.
Samuel Penney (Chairman)	19396	122	Sweetgrass growing in the Landmark area was also documented by the Idaho Native Plant Society during a botanical survey in 2022.	VEG	No text revisions made. Occurrence data for sensitive and watch species has been provided and are still accurate for the analysis. Additionally, details regarding potential impacts to sensitive and watch species is provided in Section 4.10.2 and measures proposed by Perpetua and required by the Forest Service, primarily the requirement of preconstruction surveys to identify occurrences of sensitive and watch species and then establish protection measures, would reduce Project-related impacts to these species.
Samuel Penney (Chairman)	19396	123	Rannoch rush is a perennial, herbaceous, and vulnerable plant that grows in wetlands. It is listed on the National Wetland Plant List as an obligate hydrophyte (almost always occurs in wetlands) and is documented in the Mud Lake area within 300 feet of Burntlog Road (modeled potential habitat is 850 acres).	VEG	No text revisions made. Occurrence data for sensitive and watch species has been provided and are still accurate for the analysis. Additionally, details regarding potential impacts to sensitive and watch species is provided in Section 4.10.2 and measures proposed by Perpetua and required by the Forest Service, primarily the requirement of preconstruction surveys to identify occurrences of sensitive and watch species and then establish protection measures, would reduce Project-related impacts to these species.
Samuel Penney (Chairman)	19396	124	With the exception of bent-flower milkvetch, none of these species were included in past special status surveys. Blandow's helodium moss, sweetgrass, and rannoch-rush have not been surveyed by the Forest since 2004. The Forest needs to update surveys and location information for these Forest Watch species that have occurrences and potential habitat in the Project area, including occurrences across 13 Inventoried Roadless Areas.	VEG	No text revisions made. Occurrence data for sensitive and watch species has been provided and are still accurate for the analysis. Additionally, details regarding potential impacts to sensitive and watch species is provided in Section 4.10.2 and measures proposed by Perpetua and required by the Forest Service, primarily the requirement of preconstruction surveys to

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
					identify occurrences of sensitive and watch species and then establish protection measures, would reduce Project-related impacts to these species.
Samuel Penney (Chairman)	19396	125	<p>Non-Native Plants</p> <p>The SDEIS does an inadequate job of disclosing the distribution and extent of noxious weeds and non-native plant species occurring in the Project area. Two pages dedicated to noxious and nonnative plants is insufficient. Table 3.10-6 lists noxious weeds and non-native plant species in Valley County and the analysis area and includes two species identified as "Noxious-Early Detection and Rapid Response" (yellow hawkweed (<i>Hieracium caespitosum</i>) and Syrian beancaper (<i>Zygophyllum fabago</i>)), however the SDEIS states that " [n]o known species of Early Detection and Rapid Response are known in the subregion." Please provide clarification of occurrence for these species in the SDEIS.</p>	VEG	No text revisions made. Noxious weeds are discussed in Section 3.10 and 4.10 and measures described in Chapter 2 of the EIS to reduce the establishment and spread of noxious weeds would be implemented throughout the life of the Project. Additional details are also provided in the reclamation plan.
Samuel Penney (Chairman)	19396	126	<p>According to the SDEIS, spotted knapweed (<i>Centaurea stoebe</i> ssp. <i>micranthos</i>) and rush skeletonweed (<i>Chondrilla juncea</i>) are the most extensive species in the analysis area. But the SDEIS fails to include life histories, management, spatial context, and mechanism of establishment and growth. The Vegetation Specialist Report includes maps of these species, but they lack extent (i.e., percentage distribution), and their locations are difficult to see on the maps. The maps in Appendix C of the Vegetation Specialist Report leave out most of the species listed in the SDEIS and should also include common names of these plants in the legend. The SDEIS needs to include percent occurrence by mine features - utilities, mine site, off-site facilities, and access roads.</p> <p>Without spatial context and degree of their extent (% of each in the Project area), it is difficult to understand the affected environment and environmental consequences of the proposed action. The SDEIS also narrowly focuses on noxious weeds designated by the Idaho State Department of Agriculture and does not mention other non-native plants present within the Project area, except for bull thistle (<i>Cirsium vulgare</i>). Does this mean no other non-native plants exist in the Project area? What about the presence of non-native annual grasses? The Forest needs to disclose all nonnative plants that occur in the affected environment. The existence of other non-native plant species may jeopardize reclamation efforts and fail to meet Forest Plan management direction, as well as violate other federal regulations (i.e., SMCRA).</p>	VEG	No text revisions made. Noxious weeds are discussed in Section 3.10 and 4.10 and measures described in Chapter 2 of the EIS to reduce the establishment and spread of noxious weeds would be implemented throughout the life of the Project. Additional details are also provided in the reclamation plan.
Samuel Penney (Chairman)	19396	127	The SDEIS needs to disclose any records or information about the non-native plant species' occurrences over time (i.e., what species have increased over time in the Project area; what species are likely to spread into the foreseeable future). The RCP states that Perpetua implemented a Weed Management Plan in 2015 and that studies conducted at the Project area have identified Canada thistle (<i>Cirsium arvense</i>), rush skeletonweed, spotted knapweed (<i>Centaurea</i> ssp.; three latin names are cited in the Vegetation Specialist Report), and yellow toadflax (<i>Linaria vulgaris</i>). These are worrisome plant species. The SDEIS needs to include more information about each of these species, as well as others listed in the SDEIS. For example, oxeye daisy (<i>Leuceanthemum vulgare</i>) is a species of concern because it is an aggressive invasive species that can spread quickly into undisturbed meadows and riparian areas, displace native vegetation, and produce many seeds that remain viable in the soil for several years. What management actions including monitoring has the Forest or Perpetua done to control establishment and growth of these species? Are any present on the reclaimed areas, and if yes, then how will the Forest control their spread when Perpetua disturbs these areas again under the proposed actions? The Weed Plan will be updated prior to construction and needs to be part of the FEIS so the Tribe can review it.	VEG	No text revisions made. Noxious weeds are discussed in Section 3.10 and 4.10 and measures described in Chapter 2 of the EIS to reduce the establishment and spread of noxious weeds would be implemented throughout the life of the Project. Additional details are also provided in the reclamation plan.
Samuel Penney (Chairman)	19396	129	There are three Forest Watch species mentioned in the vegetation section (3.10) of the SDEIS (Blandow's helodium moss, sweetgrass, and Rannoch-rush); all three species are considered wetland plants. Blandow's helodium moss (also named <i>Elodium blandowii</i>) forms in mats and hummocks in wet areas of the forest (e.g., fens, wetlands, and near streams). One occurrence is located near Trapper Creek within 300 feet of Burntlog Route, but there are 705 acres of mapped potential habitat.	VEG	No text revisions made. Occurrence data for sensitive and watch species has been provided and are still accurate for the analysis. Additionally, details regarding potential impacts to sensitive and watch species is provided in Section 4.10.2 and measures proposed by Perpetua and required by the Forest Service, primarily the requirement of preconstruction surveys to identify occurrences of sensitive and watch species and then establish protection measures, would reduce Project-related impacts to these species.

Samuel Penney (Chairman)	19396	130	Imperiled in Idaho, northern sweetgrass (also named Heirochloe hirta) is found in wetlands near Trapper Creek and mapped as having 996 acres of potential habitat. Sweetgrass growing in the Landmark area was documented by the Idaho Native Plant Society during a botanical survey in 2022.	VEG	No text revisions made. Occurrence data for sensitive and watch species has been provided and are still accurate for the analysis. Additionally, details regarding potential impacts to sensitive and watch species is provided in Section 4.10.2 and measures proposed by Perpetua and required by the Forest Service, primarily the requirement of preconstruction surveys to identify occurrences of sensitive and watch species and then establish protection measures, would reduce Project-related impacts to these species.
Samuel Penney (Chairman)	19396	131	Rannoch-rush is a perennial, herbaceous, and vulnerable plant that grows in wetlands. It is listed on the National Wetland Plant List as an obligate hydrophyte (almost always occurs in wetlands) and is documented in the Mud Lake area within 300 feet of Burntlog Road (modeled potential habitat is 850 acres). None of these species were included in past special status surveys.	VEG	No text revisions made. Occurrence data for sensitive and watch species has been provided and are still accurate for the analysis. Additionally, details regarding potential impacts to sensitive and watch species is provided in Section 4.10.2 and measures proposed by Perpetua and required by the Forest Service, primarily the requirement of preconstruction surveys to identify occurrences of sensitive and watch species and then establish protection measures, would reduce Project-related impacts to these species.
Samuel Penney (Chairman)	19396	132	Blandow's helodium moss, sweetgrass, and Rannoch-rush have not been surveyed by the Forest since 2004.	VEG	No further response required. General in nature or position statement.
Samuel Penney (Chairman)	19396	133	Sensitive species Least moonwort (or little grapefern) is a native wetland, perennial, facultative hydrophyte fern. It is listed on the National Wetland Plant List as a facultative perennial fern (occurs in wetlands and non-wetlands). According to the SDEIS, two subpopulations of a single occurrence occur in swales adjacent to Johnson Creek Road. To realize the full impacts on these subpopulations, the Forest needs to revisit these sites and potential habitat (838 acres), assess impacts and disclose them in the SDEIS. These sites have not been surveyed since 2005.	VEG	No text revisions made. Occurrence data for sensitive and watch species has been provided and are still accurate for the analysis. Additionally, details regarding potential impacts to sensitive and watch species is provided in Section 4.10.2 and measures proposed by Perpetua and required by the Forest Service, primarily the requirement of preconstruction surveys to identify occurrences of sensitive and watch species and then establish protection measures, would reduce Project-related impacts to these species.
Samuel Penney (Chairman)	19396	146	The Forest needs to update the SDEIS to reflect changes to whitebark pine status as an ESA-threatened species.	VEG	Text has been revised per the comment to update the status of the whitebark pine per the listing on December 15, 2022. Additionally, the analysis and required protection measures as well as mitigation measures required by the Forest Service have been added to the Final EIS, specifically in Sections 3.10, 4.10, and 5.10, as appropriate.
Samuel Penney (Chairman)	19396	179	Compost and fertilizers will likely support greater establishment and growth of noxious weeds and non-native plants.	VEG	No further response required. General in nature or position statement.
Samuel Penney (Chairman)	19396	229	4.10 Vegetation The Tribe is concerned about the irreversible and irretrievable impacts to vegetation, including the destruction and loss of ESA-threatened whitebark pine, loss of potential habitat for special-status plant species, spread of non-native and noxious, invasive plant species (on more than 3,000 acres of disturbed land), and likely permanent changes to the function and structure of vegetation that supports wildlife, nutrient cycling, and soil stability. Impacts may result in changes to the Project area that persist in perpetuity. The SDEIS discloses that land disturbed under both alternatives would not maintain and move towards Forest Plan desired conditions into the foreseeable future (> 2,000 acres under both alternatives, including >270 acres of land where mine activities would prevent the regrowth of vegetation).	VEG	No further response required. General in nature or position statement.
Samuel Penney (Chairman)	19396	230	Impacts to vegetation are greater under the preferred alternative (2021 MMP) than the Johnson Creek Road alternative. These lands currently support native vegetation that sustains terrestrial and aquatic habitats on the Forests. The proposed actions are unacceptable and inconsistent with NFMA policies, Forest Plan direction, and, most important, the Forest's trust responsibility to the Tribe.	VEG	No further response required. General in nature or position statement.
Samuel Penney (Chairman)	19396	231	The Forest needs to take a hard look at impacts to plant resources used by the Tribe, which are only briefly described in the SDEIS. Reference in the analysis should also be made to associated habitat types where these plant resources are found (i.e., impacts need to have spatial (e.g., linked with PVGs) and temporal (e.g., phenology and gathering season) context). The SDEIS fails to discuss the "so, what?" aspect of an environmental effects analysis. For example, the SDEIS describes that there will be increased habitat fragmentation for plant populations, but fails to explain where, how, when, and why it is meaningful. Under all action alternatives, construction and maintenance of utilities and access roads could fragment many wetlands indefinitely – the SDEIS needs to explain the consequences of	VEG	Text has been added per the comment. Additional information has been added to Section 3.17 and Section 3.24 of the Final EIS regarding these plant species and Section 3.10 and 4.10 is cross-referenced within Section 3.17 and 3.24.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			fragmentation to vegetation, soils, hydrology, aquatics, and wildlife. The SDEIS needs to interpret and support (using best available scientific information) the conclusory statements. The magnitude, extent, direction, duration, and speed of effects of each alternative need to be defined quantitatively and/or qualitatively. These interpretations of resource impacts should also be built on and integrated with other resources. The Forest concludes that both action alternatives will not contribute to the loss of viability of plant species within the planning area (i.e., Payette and Boise administered lands), however, the Tribe is deeply concerned that the activities will reduce viability and availability of plant species for Tribal harvest and use within the Project area, which is just as important as the entire planning area.		
Samuel Penney (Chairman)	19396	232	In many places throughout Chapter 4 (Environmental Consequences), the SDEIS discloses impacts to plants and pollinators from dust and emissions, however, the types, conditions, and seasonality of pollinators are not discussed as part of the affected environment. The SDEIS fails to include pollinators, or any invertebrate, as part of the affected environment for soils, vegetation, and wildlife. This information, including but not limited to, the diversity and abundance of pollinators that exist in the project area, needs to be a part of the SDEIS.	VEG	Text has been added to Sections 3.13 and 4.13 regarding pollinators that may occur in the analysis area.
Samuel Penney (Chairman)	19396	233	The SDEIS does not adequately analyze components or effectiveness of the RCP. If the Project is required to adhere to Forest Service-required mitigation measures, the design features and resource protection measures, and procedures in the RCP, then the SDEIS needs to consider these in the effects analysis and explain their effectiveness. The reclamation seed mixes proposed in the RCP, for example, are not reflective of the PVGs in the Project area. The likelihood that these areas will comply with NFMA policies and Forest Plan directions is low. The SDEIS even discloses that vegetation removal and tree clearing under all action alternatives would not maintain or move toward desired conditions for vegetation as described in the Forest Plans, and likely that any or all impacts may result in changes to the surrounding ecosystem that persist in perpetuity and would result in these areas not being able to meet desired conditions for the foreseeable future. The SDEIS fails to give adequate attention to the permanent loss of habitat types. Most impacts to PVGs under all action alternatives would be related to disturbance activities at the mine site and would occur in the Warm, Dry Subalpine Fir (PVG 7) and Persistent Lodgepole Pine (PVG 10) types, which are the most extensive PVGs in the analysis area. This is unacceptable.	VEG	No text revisions made. The Forest Service has approved the RCP and it has been incorporated appropriately into Section 4.10.
Samuel Penney (Chairman)	19396	234	According to the SDEIS, dust abatement measures would be used during construction, operation, and closure to reduce the amount of fugitive dust. The SDEIS provides a few scientific references but fails to disclose impacts from these measures. The SDEIS lacks relevant references as to the impacts of dust abatement chemicals on soils, vegetation, and wildlife. Magnesium chloride (MgCl ₂) and MgCl ₂ - lignin sulfonate products used to suppress dust on roadsides can damage vegetation foliage, alter soil quality, move in roadside drainages of up to 98 m from roads, and accumulate over time, often to toxic concentrations, in trees and soils. High MgCl ₂ soil concentrations from application caused mortality of Douglas-fir, lodgepole, ponderosa, and limber pines, and aspen in just two to four years. Considering the life of the Project (> 20 y), the Tribe is concerned about long-term consequences to soils and vegetation from dust abatement chemicals. The SDEIS fails to address and take a hard look at these actions, and the Tribe requests that the Forest Service use the least environmentally damaging dust suppressant, and monitor impacts to vegetation, soils, water, and terrestrial and aquatic ecosystems.	VEG	No text revisions made. Dust abatement measures would focus on confining chemical usage away from vegetation, non-disturbed soils, and any wildlife in the area. Fugitive dust control along roads would confine chemicals to the centerline of the roadway to avoid overspray onto adjacent non-disturbed areas; therefore, limiting any potential impacts to soils, vegetation, and wildlife.
Samuel Penney (Chairman)	19396	235	Impacts to Whitebark Pine The SDEIS lacks specific spatial and temporal details about the impacts to whitebark pine under each alternative, including number of individual trees and acreage associated with specific location (private versus federal land) and proposed actions (facilities, utilities). Instead, the SDEIS summarizes the total amount of impacted acres and number of individual trees removed. Without spatial reference, it is difficult to know where these impacts occur within the Project area. The SDEIS references the Stibnite Gold Project Vegetation Specialist Report Appendix F for details about the survey conducted by Tetra	VEG	Text has been revised per the comment to update the status of the whitebark pine per the listing on December 15, 2022. Additionally, the analysis and required protection measures as well as mitigation measures required by the Forest Service have been added to the Final EIS, specifically in Sections 3.10, 4.10, and 5.10, as appropriate.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			Tech, however Table F-1 is not associated with any maps or citation, and therefore lacks meaning. The Forest needs to do a better job at disclosing the impacts to whitebark pine.		
Samuel Penney (Chairman)	19396	236	Under ESA protection, it is unlawful to commit, to attempt to commit, to cause to be committed, or to solicit another to commit the following acts for whitebark pine: removal from federal lands; malicious damage or destruction on federal lands; engaging in interstate or foreign commerce; and import or export (into, out of, or through the U.S.). Actions under all alternatives, including the No Action Alternative (e.g., existing and approved activities described in the SDEIS), will harm whitebark pine. Under both action alternatives, utility activities include new and upgraded transmission lines, substations, communication towers, and repeater sites. According to the SDEIS, vegetation clearing would occur indefinitely on the new and upgraded transmission line (> 1,000 acres under both alternatives), which would impact an indefinite number of continuously-establishing seedlings as well. The proposed alternative would remove an estimated 193 trees for utilities (not counting what would be removed to maintain the transmission line ROW indefinitely), trees for access roads, and 564 trees for operations at the mine site. But these numbers are based on surveys of a previously proposed footprint (Alternative 2 from the Forests' DEIS) and are only estimates.	VEG	Text has been revised per the comment to update the status of the whitebark pine per the listing on December 15, 2022. Additionally, the analysis and required protection measures as well as mitigation measures required by the Forest Service have been added to the Final EIS, specifically in Sections 3.10, 4.10, and 5.10, as appropriate.
Samuel Penney (Chairman)	19396	238	The Tribe is concerned that the SDEIS does not contain mitigation measures or a restoration plan for the loss of whitebark pine or limber pine in the analysis area.	VEG	Text has been revised per the comment to update the status of the whitebark pine per the listing on December 15, 2022. Additionally, the analysis and required protection measures as well as mitigation measures required by the Forest Service have been added to the Final EIS, specifically in Sections 3.10, 4.10, and 5.10, as appropriate. These same measures would likely also protect limber pine as this species occurs in similar habitats (and often alongside) whitebark pine.
Samuel Penney (Chairman)	19396	239	The SDEIS is silent on impacts to limber pine and to the mutualistic relationships between five-needle pines and seed dispersers.	VEG	Text revisions have been made. Limber pine is discussed in Section 4.10.2 and many of the same protection measures for sensitive and watch plant species as well as whitebark pine would identify and minimize impacts to limber pine.
Samuel Penney (Chairman)	19396	240	It is also unclear in the SDEIS what will happen to whitebark pine removed under each action alternative, and whether the Forest will require Perpetua to restore impacted habitat.	VEG	Text has been revised per the comment to update the status of the whitebark pine per the listing on December 15, 2022. Additionally, the analysis and required protection measures as well as mitigation measures required by the Forest Service have been added to the Final EIS, specifically in Sections 3.10, 4.10, and 5.10, as appropriate.
Samuel Penney (Chairman)	19396	242	Impacts to Sensitive and Forest Watch Species Actions under the preferred alternative would cause adverse impacts to known occurrences of Sensitive and Forest Watch species including bent-flower milkvetch (Cinnabar Peak subpopulation), least moonwort (wetlands along Johnson Creek Road), Blandow's helodium (wetlands along Burntlog Route), sweetgrass (wetlands near Burntlog Route), Sacajawea's bitterroot (along new and upgraded transmission line), and rannoch-rush (wetlands near Burntlog Route). In some cases, actions would completely remove individual plants and could result in conditions that would no longer support the species (e.g., for Blandow's helodium and sweetgrass). The Tribe is concerned about these impacts to known occurrences, and is also concerned that because the Forest has not surveyed for occurrences since 2004 for some of these plants, that direct impacts to individual plants and their habitats could be greater than realized. Surveys for occurrences of other plant species with potential habitat under both alternatives should also be conducted and disclosed to the Tribe prior to any decision.	VEG	No text revisions made. Occurrence data for sensitive and watch species has been provided and are still accurate for the analysis. Additionally, details regarding potential impacts to sensitive and watch species is provided in Section 4.10.2 and measures proposed by Perpetua and required by the Forest Service, primarily the requirement of preconstruction surveys to identify occurrences of sensitive and watch species and then establish protection measures, would reduce Project-related impacts to these species.
Samuel Penney (Chairman)	19396	244	The SDEIS also fails to consider impacts to vegetation considering projected climate shifts which may exacerbate reclamation efforts (estimated to take place over several decades). The Project area encompasses alpine and subalpine forests and riparian forest that are vulnerable to projected changes in climate, yet the SDEIS falls silent on these vulnerabilities and how the actions may complicate post-mining recovery and land uses.	VEG	No text revisions made. Climate Change is discussed in Section 3.4, 4.4, and 5.4.
Samuel Penney (Chairman)	19396	246	Impacts to Non-Native Plants	VEG	No text revisions made. Noxious weeds are discussed in Section 3.10 and 4.10 and measures described in Chapter 2 of the EIS to reduce the establishment and spread of noxious weeds

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			The SDEIS fails to discuss the "so, what" aspect of an environmental effects analysis regarding noxious weeds and non-native plants. The SDEIS also fails to describe the most concerning noxious weeds and non-native plants, and estimate how and to what extent they could spread under the proposed actions. What is their preferred habitat? What conditions support establishment and growth? Discussing their life histories can help create effective control measures.		would be implemented throughout the life of the Project. Additional details are also provided in the reclamation plan.
Samuel Penney (Chairman)	19396	254	The SDEIS should also reference the plant species and include it in the mitigation plan for planting and should suggest removing species from the site and replanting them at the mitigation site.	VEG	No text revisions made. Section 2.4.9 of the EIS includes details on reclamation, required protection measures by the Forest Service, and EDFs proposed by Perpetua.
Samuel Penney (Chairman)	19396	379	The SDEIS fails to analyze impacts to large or medium-size forest stands that have species composition required to achieve old forest habitat for applicable PVGs. According to the Boise National Forests Plan, management actions within large or medium size class forested stands that have the species composition required to achieve old forest habitat for the applicable PVGs shall contribute to or not preclude restoration of old forest habitat (Boise Forest Plan Standard WIST 09). The SDEIS fails to analyze actions that would not retain forest stands that meet the definition of old forest habitat for the applicable PVGs, management actions are permitted in such stands as long as they will continue to meet the definition of old forest habitat (Boise Forest Plan Standard WIST08).	VEG	No text revisions made. The vegetation analysis, including Forest Service-specific data on PVGs and other specific species data is included in Sections 3.10 and 4.10. Outside of permanently disturbed areas, the reclamation plan addresses replanting of trees in areas to be reclaimed based on previously occupied vegetation characteristics, including species composition, density, and stand structure.
Samuel Penney (Chairman)	19396	410	5.10 Vegetation: General Vegetation Communities, Botanical Resources, and Non-native Plants Under all alternatives, RFFAs, past, and present actions would impact vegetation communities, occurrences and habitats of special status plants (e.g., whitebark pine), and distribution of noxious weeds and non-native plants. The Tribe is concerned that perpetual disturbances from mining coupled with wildland fire, climate change, forest management, and other human activities will cause irreversible and long-term damage to vegetation communities within and adjacent to the Project. Acres disturbed by the Project plus acres disturbed by other activities (e.g., exploration, transportation, wildland fire) have the cumulative potential to increase the occurrence of noxious weeds and non-native plants. If the Forest allows this Project to violate many Forest Plan Standards and Guidelines and proceed as planned, then the footprint of "sacrifice areas" will continue to grow. The Forests' actions will pave the way for future mining activities and thus create a great magnitude of adverse and long-term impacts to treaty resources.	VEG	No further response required. General in nature or position statement.

Wetlands and Riparian Resources

Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	38	VI. THE SDEIS LACKS ANALYSIS OF CWA 404 b(1) GUIDELINES In addition to the above comments addressed to the Forest Service and the Army Corps of Engineers (Corps), the following additional comments pertain more directly to the Corps' review of Perpetua's application for a CWA Section 404 permit, although they should be considered by the Forest Service too, as the Forest Service cannot authorize any activities that could violate the CWA or other federal or state laws/regulations. Congress enacted the CWA in 1972, to "restore and maintain the chemical, physical, and biological integrity of the Nation's waters." 33 U.S.C. § 1251(a). The Act sets several goals, including attainment and preservation of "water quality which provides for the protection and propagation of fish, shellfish, and wildlife..." Id. § 1251(a)(2). To further its goals, the Act prohibits "discharge of any pollutant" into navigable waters except in accordance with the CWA terms. Id. § 1311(a). The Corps issues permits for the discharge of dredged or fill material pursuant to section 404 and subject to the Corps' and EPA's 404(b)(1) Guidelines (Guidelines). 33 U.S.C. §1344; 40 C.F.R. pt. 230. Corps regulations governing the issuance of Section 404 permits declare that "[m]ost wetlands constitute a productive and valuable public resource, the unnecessary alteration or destruction of which should be	WET	Compliance with the 404(b)1 Guidelines is determined by the USACE following submission of a complete 404 permit application from the proponent. No application had been submitted at the time of the SDEIS. However, the USACE and the Forest Service have ensured that the procedural requirements to include the development and evaluation of the Action Alternatives, resource identification, and the evaluation of effects considered in the guidelines were fully analyzed in the NEPA effort which will inform that future determination. Relevant sections informing the varying parts include, but are not limited to; Chapter 2, and Sections 4.8, 4.9, 4.10, 4.11, 4.12,4.13, 4.18, 4.19, and 4.23, and their counterpart sections within the EIS.

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>discouraged as contrary to the public interest.” 33 C.F.R. § 320.4(b)(1); see also id. § 320.4(b)(2) (identifying eight types of wetland functions important to the public interest).</p> <p>The Corps’ and EPA’s 404(b)(1) Guidelines impose important limitations on the Corps’ ability to issue a Section 404 permit. 40 C.F.R. pt. 230. The Corps must ensure compliance with the 404(b)(1) Guidelines before issuing a permit. The Guidelines impose important limitations on when a Section 404 permit may be issued. Id. The Guidelines prohibit the permitting of any discharge of dredged or fill material: (1) if there is a practicable alternative to the proposed discharge; (2) if the discharge causes or contributes to violations of applicable state water quality standards; (3) if the discharge will cause or contribute to significant degradation of the environment; or (4) unless all appropriate steps have been taken to minimize potential adverse impacts. Id. § 230.10. The 404(b)(1) Guidelines provide that significant adverse effects on human health or welfare; aquatic life and other water dependent wildlife; aquatic ecosystem diversity, productivity, and stability; or recreational, aesthetic, and economic values are effects contributing to significant degradation. Id. § 230.10(c)(1)–(4). These factors both individually and cumulatively must be considered when evaluating the specific details of the 404 application.</p> <p>The Corps cannot authorize a discharge without “sufficient information to make a reasonable judgment as to whether the proposed discharge will comply with [the Section 404(b)(1)] Guidelines.” Id. § 230.12(a)(3)(iv); see 33 C.F.R. §§ 320.2(f) and 320.4(a)(1). EPA notes that: the record must contain sufficient information to demonstrate that the proposed discharge complies with the requirements of Section 230.10(a) of the Guidelines. The amount of information needed to make such a determination and the level of scrutiny required by the Guidelines is commensurate with the severity of the environmental impact (as determined by the functions of the aquatic resource and the nature of the proposed activity) and the scope/cost of the project.</p> <p>As discussed herein, the proposed discharge does not comply with the 404(b)(1) Guidelines. Pursuant to the Guidelines, no discharge of dredged or fill material shall be permitted if, among other things, a practicable alternative to the proposed discharge would have less of an adverse impact on the aquatic ecosystem. 40 C.F.R. § 230.10. The Corps also cannot authorize any discharge of dredged or fill material that will cause or contribute to significant degradation of the waters of the United States. Id. § 230.10(c). The “degradation or destruction of special aquatic sites, such as filling operations in wetlands, is considered to be among the most severe environmental impacts covered by the[] Guidelines.” Id. § 230.10(d).</p> <p>Under the 404(b)(1) guidelines, the Corps is required to consider the following effects, individually and collectively, that contribute to significant degradation:</p> <p>(1) Significantly adverse effects of the discharge of pollutants on human health or welfare, including but not limited to effects on municipal water supplies, plankton, fish, shellfish, wildlife, and special aquatic sites.</p> <p>(2) Significantly adverse effects of the discharge of pollutants on life stages of aquatic life and other wildlife dependent on aquatic ecosystems, including the transfer, concentration, and spread of pollutants or their byproducts outside of the disposal site through biological, physical, and chemical processes;</p> <p>(3) Significantly adverse effects of the discharge of pollutants on aquatic ecosystem diversity, productivity, and stability. Such effects may include, but are not limited to, loss of fish and wildlife habitat or loss of the capacity of a wetland to assimilate nutrients, purify water, or reduce wave energy; or</p> <p>(4) Significantly adverse effects of discharge of pollutants on recreational, aesthetic, and economic values. § 230.10(c).</p> <p>As shown throughout these comments, the proposed mine will violate these requirements and thus a 404 permit cannot be issued.</p> <p>The Corps is required to base this determination on factual determinations, evaluations, and tests required under the guidelines, and to focus, in particular, on the persistence and permanence of the</p>		

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>effects. Id. The Guidelines require the Corps to make certain factual determinations addressing the potential short-term or long-term effects of a proposed discharge of dredged or fill material on the physical, chemical, and biological components of the aquatic environment. This includes determinations on (a) physical substrate; (b) water circulation, fluctuation, and salinity determinations; (c) suspended particulate/turbidity determinations; (d) contaminant determinations; (e) aquatic ecosystem and organism determinations; (f) proposed disposal site determinations; (g) determinations of cumulative effects on the aquatic ecosystem; and (h) determinations of secondary effects on the aquatic ecosystem. Id. § 230.11(a)–(h).</p> <p>When a project is not “water dependent,” as in the case of the mine, and the project would fill “special aquatic sites,” including wetlands, the Corps’ regulations create a rebuttable presumption that there are practicable and environmentally preferable alternatives, and such alternatives are presumed to have less adverse impact unless “clearly demonstrated” otherwise. 40 C.F.R. § 230.10(a)(3). This substantive requirement mandates the Corps to select the least environmentally damaging practicable alternative (LEDPA).</p> <p>An alternative is practicable “if it is available and capable of being done after taking into consideration cost, existing technology, and logistics in light of overall project purposes.” 40 C.F.R. § 230.10(a)(2). Practicable alternatives include “activities which do not involve a discharge of dredged or fill material,” as well as “discharges of dredged or fill material at other locations” where such discharges would result in fewer impacts to the aquatic environment. § 230.10(a)(1). The applicant has the burden of demonstrating that no feasible alternative exists, and the Corps must engage in a reasoned analysis of this issue.</p> <p>The Corps cannot blindly and uncritically accept an applicant’s study of alternatives and its assertions that no practicable alternative exists. Under the regulations, any “practicable” alternative to achieve the basic and overall project purposes must be determined to be cost-effective, when viewed from the perspective of the industry as a whole. The financial circumstances of a particular applicant are not considered relevant if an alternative could be achieved practicably by a “typical” applicant. The preamble to the 404(b)(1) regulations states: “Our intent is to consider those alternatives which are reasonable in terms of the overall scope/cost of the proposed project. The term economic might be construed to include consideration of the applicant’s financial standing, or investment, or market share, a cumbersome inquiry which is not necessarily material to the objectives of the Guidelines. We consider it implicit that, to be practicable, an alternative must be capable of achieving the basic purpose of the proposed activity.”</p> <p>But the least environmentally damaging practicable alternative need not be the least costly, nor the most profitable. The regulations presume that less environmentally damaging alternatives are available to the applicant and practicable, unless the applicant clearly demonstrates otherwise. In the absence of such a clear showing, the Corps is required to deny the permit application. See 40 C.F.R. § 230.12(a)(3)(i), (iv). Thus, in this case, the preferred tailings location in upper Meadow Creek does not comply with these requirements.</p> <p>To ensure the mandatory CWA requirements are satisfied, the Corps must evaluate the direct, secondary, and cumulative impacts of the activity on a number of resources. See, e.g., 33 C.F.R. §§ 320.4(a)(1), 336.1(c)(5) (endangered species), 336.1(c)(8) (fish and wildlife); 40 C.F.R. §§ 230.11(a)-(h), 230.20-23 (aquatic ecosystem), 230.53 (aesthetics). The EPA Guidelines require the Corps to make detailed factual determinations regarding the individual and collective effects associated with the discharge activity, and “no discharge of dredged or fill material shall be permitted which will cause or contribute to significant degradation of the waters of the United States.” 40 C.F.R. §230.10(c). “Findings of significant degradation related to the proposed discharge shall be based upon appropriate factual determinations, evaluations, and tests required by subparts B and G . . . , with special emphasis on the persistence and permanence of the effects outlined in those subparts.”</p>		

Author	Comment Letter	Comment Number	Comment	Comment Category	Comment Response
			<p>The “factual determinations, evaluations, and tests” mandated in subpart B include Section 230.11, which requires that “[t]he determinations of effects of each proposed discharge shall include the following:</p> <p>(h) Determination of secondary effects on the aquatic ecosystem.</p> <p>(1) Secondary effects are the effects on an aquatic ecosystem that are associated with a discharge of dredged or fill materials, but do not result from the actual placement of the dredged or fill material. Information about secondary effects on aquatic ecosystems shall be considered prior to the time final section 404 action is taken by permitting authorities.</p> <p>(2)... Activities to be conducted on fast land created by the discharge of dredged or fill material in waters of the United States may have secondary impacts within those waters which should be considered in evaluating the impact of creating those fast lands. 40 C.F.R. §230.11(h)(emphasis added).</p> <p>The Guidelines also require the Corps to “control runoff and other discharges from activities to be conducted on the fill.” Id. § 230.77(a).</p> <p>Thus, the secondary effects that the Corps is required to consider are not limited in time or space to just the initial discharge. Rather, they encompass all activities and impacts “associated with” the fill activities. Furthermore, “[f]undamental to these Guidelines is the precept that dredged or fill material should not be discharged into the aquatic ecosystem, unless it can be demonstrated that such a discharge will not have an unacceptable adverse impact either individually or in combination with known and/or probable impacts of other activities affecting the ecosystems of concern.” 40 C.F.R. § 230.1(c)(emphasis added).</p> <p>Indeed, according to the regulatory preamble to EPA’s promulgation of the 404(b)(1) Guidelines: “in authorizing a discharge which will create fast lands the permitting authority should consider in addition to the direct effects of the fill itself the effects on the aquatic environment of any reasonably foreseeable activities to be conducted on that fast land.” And, regarding the “factual determinations” in § 230.11 (including secondary effects in 230.11(h)), EPA stated: “in response to many comments, we have moved the provisions on cumulative and secondary impact to the Factual Determination section to give them further emphasis. We agree that such impacts are an important consideration in evaluating the acceptability of a discharge site.”</p> <p>In another rulemaking implementing the CWA, the Corps and EPA reiterated that the Corps’ must fully consider the indirect/cumulative impacts as well as direct impacts from the discharge itself: EPA’s long-standing interpretation of Section 404, as reflected in the Section 404(b)(1) Guidelines, demonstrates that EPA and the Corps are not limited to considering solely the environmental effects of the discharge itself. The Guidelines expressly require consideration of “secondary effects,” which are defined as: effects on an aquatic ecosystem that are associated with a discharge of dredged or fill materials, but do not result from the actual placement of the dredged or fill material. 40 CFR § 230.11(h).</p> <p>EPA and the Corps believe that considering the primary and secondary effects of a discharge is clearly consistent with the language and intent of Section 404 to ensure protection of the aquatic system from effects associated with the discharge of dredged and fill material.</p> <p>The agencies highlighted the Tenth Circuit’s decision in <i>Riverside Irrigation Dist. v. Andrews</i>: In this case, the Corps denied nationwide permit coverage for the construction of a dam, the operation of which would have resulted in depleted stream flows that would adversely affect habitat of an endangered species. Even though the discharge of fill material itself to construct the dam would not have had an adverse impact, the court held that the CWA authorized the Corps to consider the total environmental impact of the discharge, including indirect effects such as the impact of the operation of the dam on flows downstream and associated wildlife impacts. The court in <i>Riverside</i> concluded that “the Corps was required to consider all effects, direct and indirect, of the discharge for which authorization was sought.” Additional courts have acknowledged the Corps’ duty to consider secondary and cumulative effects resulting from issuance of a 404 permit. In <i>Greater Yellowstone Coalition v. Flowers</i>, the Tenth Circuit upheld a Corps 404 permit in part because of the Corps’ analysis of the “upland aspects” of the entire</p>

			<p>development, not just the limited direct impact of the fill itself: “the Corps’ §404(b)(1) analysis should, and we believe did, take into account the impact of the Canyon Club development as a whole on bald eagle nesting and foraging habitat.” The court highlighted the Corps’ requirement to consider the impacts on the “aquatic ecosystem,” which includes “habitat for interrelated and interconnecting communities and populations of plants and animals.” In confirming the need to consider the adverse impact of the “development as a whole” on wildlife habitat and species, the court further found that: “A discharge of dredged or fill material may adversely affect these species either by directly impacting these [wildlife habitat] elements, [citing §230.30(b)(2)], or by ‘facilitating incompatible activities,’ id., § 230.30(b)(3).” For the Stibnite Gold Project, there is no question that issuance of the 404 Permit “facilitates incompatible activities” of the mine’s construction and operations, which will adversely affect wildlife and habitat.</p> <p>In <i>Sierra Club v. Van Antwerp</i>, the plaintiffs challenged the issuance of Section 404 permits to limestone mining companies. In order to determine whether the permitted activities would cause or contribute to “significant degradation” of the aquatic ecosystem, “[t]he Court must decide whether the Corps considered, as required by the CWA and implementing regulations, as well as NEPA, the significant adverse effects on municipal water supplies (which were a reasonably foreseeable result of the mining).”</p> <p>In <i>Sierra Club v. U.S. Army Corps of Engineers</i>, the plaintiffs challenged the issuance of a 404 permit for a stretch of new highway. The court relied on the “secondary effects” analysis requirements in 40 C.F.R. § 230.11(h), and the “cumulative effects” determinations in § 230.11(g), to find that the Corps failed to consider the “reasonably foreseeable development” and cumulative effects on the nearby operation of a dam and associated water flow conditions.</p> <p>The same was true in <i>Fox Bay Partners v. U.S. Corps of Engineers</i>, where the court upheld the Corps’ denial of a 404 permit for a commercial marina. The court relied on §230.11(h) and § 230.10(c) to find that “the Corps must look not only at the direct effects of a discharge but also at the indirect effects.” There, even though “[n]o one claims that the proposed fill or construction [of a marina boat ramp] itself will cause a significant degradation of the waters of the Fox River and Chain-O-Lakes,” the court found that the Corps properly considered the degradation that would result from increased boat traffic on the river and lakes that would result from building the boat ramp.</p> <p>The court’s analysis in <i>Saylor Park Vill. Council v. U.S. Army Corps of Engineers</i>, is also applicable here, as the court enjoined the upland development associated with a 404 permit for a barge facility on the Ohio River, where “the upland portion... would be practically useless without the water-based portion” and the upland development would have potential adverse visual effects on nearby historic properties. The court highlighted the need for an injunction of the entire project, including the upland portion, as “Federal courts have recognized that both economic pressure and regulatory inertia may substantially and improperly impact the decision-making of a federal agency.”</p> <p>In <i>Save Our Sonoran v. Flowers</i>, a case challenging a 404 permit, the court upheld a preliminary injunction against the entire development, despite the fact that the actual acreage of the waters of the United States (WOTUS) discharge was limited. There, the Corps failed to review the impacts from the project as a whole, focusing only on the limited direct impacts from the fill discharge. “[B]ecause the uplands are inseparable from the washes, the district court was correct to conclude that the Corps’ permitting authority, and likewise the court’s authority to enjoin development, extended to the entire project.”</p> <p>Because this project’s viability is founded on the Corps’ issuance of a Section 404 permit, the entire project is within the Corps’ purview. <i>SOS</i> makes this clear. 408 F.3d at 1124. In <i>SOS</i>, we affirmed an injunction barring any development pending adequate environmental review. We did so “[b]ecause no development could occur without impacting jurisdictional waters.”</p> <p>The Corps cannot issue a 404 permit if it “would be contrary to the public interest.” 33 C.F.R. § 320.4(a)(1). This requires the Corps to consider “the probable impacts” of a proposed project on “[a]ll factors which may be relevant to the proposal[,] including the cumulative effects.” <i>Id.</i> “Evaluation of the</p>

			<p>probable impact which the proposed activity may have on the public interest requires a careful weighing of all those factors which become relevant in each particular case.”</p> <p>All factors which may be relevant to the proposal must be considered including the cumulative effects thereof: among those are conservation, economics, aesthetics, general environmental concerns, wetlands, historic properties, fish and wildlife values, flood hazards, floodplain values, land use, navigation, shore erosion and accretion, recreation, water supply and conservation, water quality, energy needs, safety, food and fiber production, mineral needs, considerations of property ownership and, in general, the needs and welfare of the people.</p> <p>The Corps must fully consider the impacts from the entire mine in making its public interest determination. “To require [the Corps] to ignore the indirect effects that would result from its actions would be to require it to wear blinders that Congress has not chosen to impose.” In addition to the above-analyzed cases, the Ninth Circuit has recognized the Corps’ duty to consider these impacts in order to ensure that issuance of the 404 permit is in “the public interest.” In Ocean Advocates, after finding that the Corps failed to consider the cumulative impacts from increased shipping traffic resulting from the issuance of a 404 permit for an oil refinery dock, the court noted that upon remand and consideration of these effects, “the Corps may impose conditions on the operation of permitted terminals at any time ‘to satisfy legal requirements or to otherwise satisfy the public interest.’ 33 C.F.R. § 325.4(a).”</p> <p>In Clatsop Residents Against Walmart v. U.S. Army Corps of Engineers, the court upheld a Corps 404 permit needed to construct a Walmart, including the Corps’ public interest review, because the Corps had “balanced the ‘benefits which reasonably may be expected to accrue from the proposal... against its reasonably foreseeable detriments.’ 33 C.F.R. § 320.4(a)(1),” which included the potential indirect detrimental effects of the Walmart “on small businesses.”</p> <p>The same was true in Greater Yellowstone Coalition, discussed above, where the Corps successfully argued to the court that it properly considered the impacts of the “development as a whole” on wildlife and habitat, not just impacts from the fill itself. The Corps had argued that the impacts of a proposed project “beyond those associated with the proposed discharge into waters of the United States – such as the environmental impacts of upland aspects of the overall project – are for the most part meant to be addressed... through the Corps’ public interest review,” and that the Corps had “thoroughly considered and addressed the impacts on bald eagles from upland aspects of the proposed Project as part of its public interest and NEPA reviews.” If the Corps properly considered in its public interest determinations these larger regional cumulative effects to wildlife from the golf course development in Greater Yellowstone, and on the regional economy and traffic resulting from the Walmart project in Clatsop, then it certainly must consider the cumulative and indirect impacts from construction and operation of the Stibnite Gold Project and all associated facilities and impacts – impacts that show the mine/project is not in the public interest and thus the 404 permit cannot be issued.</p>		
Bonnie Gestring (Northwest Program Director, Earthworks) and seven others	17634	39	<p>The 404(b)(1) Guidelines also prohibit the Corps from issuing a 404 permit “unless appropriate and practicable steps have been taken which will minimize potential adverse impacts of the discharge on the aquatic ecosystem.” 40 C.F.R. § 230.10(d). Those seeking a 404 permit must mitigate the impacts of the proposed dredge and fill activities by “avoiding, minimizing, rectifying, reducing, or compensating for resource losses.” 33 C.F.R. § 320.4(r)(1). The purpose of the compensatory mitigation program is to “offset unavoidable impacts to waters of the United States authorized through” 404 permits. 40 C.F.R. § 230.91(a)(1). See also Id. § 230.93(a). Mitigation is required for “significant resource losses which are specifically identifiable, reasonably likely to occur, and of importance to the human or aquatic environment.” 33 C.F.R. § 320.4(r)(2). These adverse effects to aquatic resource functions, whether direct or indirect, must be mitigated. Id.; 40 C.F.R. § 230.93(a).</p> <p>Additionally, under NEPA, an EIS must: (1) “include appropriate mitigation measures not already included in the proposed action or alternatives,” 40 C.F.R. § 1502.14(f), and (2) “include discussions of... Means to mitigate adverse environmental impacts (if not already covered under 1502.14(f)).” 40 C.F.R. § 1502.16(h). “All relevant, reasonable mitigation measures that could improve the project are to be identified, even if they are outside the jurisdiction of the lead agency or the cooperation agencies...”</p>	WET	<p>Compliance with the 404(b)(1) Guidelines is determined by the USACE following submission of a complete 404 permit application from the proponent. No application had been submitted at the time of the SDEIS. However, the USACE and the Forest Service have ensured that the procedural requirements to include the development and evaluation of the Action Alternatives, resource identification, and the evaluation of effects considered in the guidelines were fully analyzed in the NEPA effort which will inform that future determination. Relevant sections informing the varying parts include, but are not limited to; Chapter 2, and Sections 4.8, 4.9, 4.10, 4.11, 4.12, 4.13, 4.18, 4.19, and 4.23, and their counterpart sections within the EIS.</p> <p>The Agencies, as well as Perpetua have developed EDFs which further avoid, minimize, or eliminate identified effects, as well as developed mitigation in addition what is proposed by Perpetua. These efforts are described in detail in the SDEIS (Section 2.4.9). Additional refinement of conceptual plans, to include a Compensatory Mitigation Plan will be submitted by the Applicant as part of the submission of a 404 permit application. The USACE will</p>
